If isms are indeed shown to relate to important outcomes, it is unclear about how to best use them to improve outcomes for individuals. One potentially fruitful use would be in providing feedback to students and employees as to how their unstated assumptions and values influence both their behavior and their interpretation of the events that happen at school and work.

Conclusion

Each of us has a set of social attitudes and beliefs that guide our perception and behavior as we traverse life. To witness their power in everyday events, one merely needs to turn on the television or read the news. Once one is aware of these isms dimensions, it is clear that nearly (or probably) all major social and political events are heavily influenced by them. We suspect that they also have a profound influence in nearly all minor everyday events. As such, a further exploration of these dimensions has the potential to greatly understand our understanding of human behavior in general, and our prediction of important performance outcomes more specifically.

Abstract

Social business deals with economic organizations oriented to social value creation. It is a new concept integrating multiple dimensions and meanings, including managerial experiences of public, private, and nonprofit organizations. Social business includes contributions from corporate social responsibility, nonprofit management, social entrepreneurship, and inclusive business (i.e., bottom of the pyramid). The concept is being consolidated by the evolution of relationships between business and society in the twenty-first century.

Introduction

The core concept of social business is economic activities with a priority aim to social value creation. It is a new integrative concept covering multidimensional meanings. There is an overlap of conceptual developments and managerial practices. The concept of social business is the result of contributions from corporate social responsibility (CSR), nonprofit organizations (NPOs), social entrepreneurship (SE), and base of the pyramid/inclusive business (BoP/IB).

CSR was the original concept and, along with environmental sustainability, became a fashion in management during the first decade of the twenty-first century. CSR originally was conceived as ethics and moral obligations, related to altruistic or philanthropic motives, but it has moved to be considered by many as social investments and plain good business. Such claim is still in debate, however. The evolution of CSR included practices of socially responsible investments, stakeholder management, the new philanthropy, and International Organization of Standardization (ISO) standard 26000.

NPOs and management are studied in and include an array of names and institutions, such as nongovernmental organizations (NGOs), charitable organizations, philanthropic foundations, cooperatives, civil society organizations, and so on. The majority of NPOs now get more than half of their income from self-generated income. The literature about NPO has focused on the professionalization, actual social impact, and financial sustainability of the organization. A key part of research has been about strategic alliances between sectors. NPO started by incorporating the best practices of for-profit management tools, but increasingly it is aimed at adapting and developing its own specific management concepts. Furthermore, the blurring of borders between public, private, and civic sectors is challenging NPOs in three ways. First, the changing challenges of the top management in respect to mission, governance, strategy, accountability, and social impact assessment. Second, the need to explore new models to gain resources, such as foundations as a legal form to secure financial resources, revenue-based nonprofits, or volunteering. Third, the discussions on the blurring of sector borders affect the ongoing question of effective education for nonprofit managers.

SE is a new concept undergoing debates about its very nature. It consists of innovative social value creation by organizations from public, private, civic, and hybrid sectors. SE is a source of social change, particularly when the organization can be replicated in other environments. Research on social entrepreneurs often contrasts them with for-profit entrepreneurs, but no conclusive evidence has been reached. Research has focused on the creation of social ventures, the measurement of social impact, and theoretical constructs development. SE is undergoing consolidation as a unified concept, and it is getting contributions from psychology, management, and economics.

BoP/IB are increasingly interchangeable terms, but the BoP was originated by scholars, whereas IB has been used more by practice-oriented and multilateral international organizations. The main idea is to alleviate poverty by integrating low-income citizens as consumers, employees, producers, suppliers, distributors, retailers, and entrepreneurs in the value chain of large companies. The best case of this BoP/IB concept is the microfinance field, in which results have been proven to benefit everyone involved. This approach is directly related to CSR and focus on the management of stakeholders and social capital.

Yunus (2008) restricted the concept of social business to for-profit business with a social aim, while our definition is wider, covering for-profit organizations as well as NPOs that engage in economic activities for social value creation. The following sections discuss the four issues of social business in more detail.

Corporate Social Responsibility

Where Does CSR Come From?

Traditionally businesses have felt the need to contribute to society, particularly in those times in which segments of society have demonstrated strong needs, like in the case of pervasive poverty, immigration, natural disasters, and the like. Company actions represented an extension of the spirit of individual solidarity, framed in the context of philanthropy (love for mankind). Some concerned businesspersons like Carnegie and Rockefeller in the United States and Cadbury in the United Kingdom in the early twentieth century and Bill Gates and Warren Buffet in the early twenty-first century, saw the

importance of complementing the actions (or failures) of governments in promoting society's development and contributed to financing schools, libraries, health facilities, and research among others. This support for society has been carried out with their own money. On many occasions, corporate resources are used to enhance society's well-being, with or without the expectation that they will enhance company profits. When they are related, the term strategic philanthropy often is used. To enhance impact, these resources can be managed with corporate principles and sometimes are called 'philanthrocapitalism' or 'venture philanthropy' (Porter and Kramer, 2002).

Where Is CSR Now?

In the mid-twentieth century, after World War II, the ideas of CSR developed further, and many companies began to see a responsibility toward society – some still out of solidarity but others out of enlightened self-interest. These companies realized that a developed society could be good for business. Research and practice evolved from the explicitly normative and ethics-oriented arguments to implicitly normative and performance-oriented managerial studies and practices (Lee, 2008). At this point, the concepts of CSR (Carroll and Buchholtz, 2011) developed to reflect the fact that companies used corporate resources for the good of society and the corporation to account for the impact on society and the environment of their activities. The modern concept includes concern for the impact on all the parties affected by company activities, in this context called 'stakeholders.' Obviously, this concern takes many different forms and includes many different parties, from employees and customers all the way to communities and the natural environment. In many cases, these stakeholders make their voices heard spontaneously, particularly in the case of corporations with large impacts, but in all cases, it is important for the company to engage in stakeholder management through consultation and to assess impact and obtain feedback.

To guide the implementation of these activities in all types of institutions the International Standards Organization produced the ISO 26000 Guidance for Social Responsibility Standard, which unlike other ISO Norms, is noncertifiable (ISO, 2011).

Within these basic ideas, there are very large variations in company behavior, depending on the context in which they operate; the strength of existing regulations and enforcements; the level of development of civil society, media, and financial markets; and particularly the relative power and willingness of consumers or client to exercise their rights. There can be companies for which the responsibility stops at complying with the law; for others, it will include actions that go beyond the law, either because the law or its enforcement are weak (as in developing countries) or because they see the value of being responsible in the form of risk mitigation of future problems or to gain the favor of the market for responsibility – that is, all stakeholders.

CSR in the second decade of the twenty-first century is a management strategy that not only includes the management of impacts on society but also tries to capture the potential benefits from the responsibility vision. One way to look at this idea is through the concern for a triple bottom line – that is, concern for the financial, social, and environmental results, and not just the traditional financial profitability, developed in the late-twentieth century. Its actual implementation will depend on the corporation's degree of responsible development, the context of time and place, the type of business, reactions of stakeholders, government and civil development, and society's needs and expectations. There are large variations in responsible practices between corporations operating in well-developed markets and in less developed ones, from large corporations to small companies, from broadly held corporations with anonymous, and many times short-term, shareholders to closely controlled and family-owned corporations. The motivations of the corporations and the impact that their responsible practices have on their own performance through the reactions of stakeholders determine their responsibility strategies.

These variations include a core of responsible practices that all companies should have, starting with the compulsory compliance with the law, responsible products and procurement, employee welfare, care for environmental resources among others, but beyond these practices, there are many variants. Some take a broader view of the contribution to society and to economic development through IB, SE, and business at the bottom of the pyramid, which will be discussed in the following section. In many cases, through the extensive use of natural resources, particularly air, water, and energy, corporations have a significant impact on the environment and need to ensure environmental sustainability through mitigating, offsetting, and undoing their impacts (Vezzoli and Manzini, 2010).

To stimulate responsible practices in corporations through their access to capital and to try to capture the expected larger benefits of responsible corporations, a field of socially responsible investment has been developed that seeks to invest directly, or indirectly through investment funds, in these corporations. The selection criteria vary widely, from simple negative screening (eliminating companies with certain products or practices) to positive screening (looking for specific or general responsible practices) (Fung et al., 2010).

Still, in many corporations, to a larger or lesser extent, 'greenwashing' will be found. This is the traditional exploitation of imperfections in the markets and asymmetries in information by some companies to capture the benefits of corporate responsibility without the corresponding costs.

Where Is CSR Going?

In the end, all of these ideas converge into sound management practices. In the future, there should be no need to talk about CSR, or any other responsibility concepts, as all will boil down to good management. CSR simply will be good management. Nevertheless, research will continue to be in segments, given the complexity of the issues. In the near future, competition will force corporations to be responsible if they want to survive. Advances in information technology and dissemination will provide better knowledge to all actors, and the possibilities for stakeholders to influence will be increased, forcing corporations to be responsible. Corporations will endeavor to be financially, socially, and environmentally sustainable.

Managing Nonprofit Organizations

Where Are NPOs Now?

This section seeks to take stock of the selected research on managing NPOs. It starts from the assumption that research on nonprofit management sometimes explicitly, but in most cases implicitly, intends to professionalize the amateur administration assumed for many NPOs.

Although the focus on professionalization has been given since the beginning of nonprofit management research in the 1970s, the research agenda has changed: Originally, scholars mainly focused on transferring proved management instruments from profit enterprises to NPOs, in areas such as accounting, human resource management, or strategic planning. The increasing financial scarcity since the turn of the millennium, however, has strengthened scholars' interests in effective fund-raising and marketing of NPOs (Helmig et al., 2004). Since then, the borders among the social, markets, and public sector have blurred (Evers, 2005).

Where Are NPOs Going?

In light of the difficulties to hold up the former distinction among the three sectors, scholars adapt their research agenda in three ways.

Research on Top Management

The blurring of sector borders challenges executive directors and board directors twofold (Young, 2008). First, scholars argue that NPOs play an increasingly critical role in the development of national economies and societies worldwide. They see a growing importance of NPOs in influencing international affairs in such fields as international trade. The question in this research field is how NPOs can support governmental policy making in solving international social and ecological issues. This rising interest of scholars is documented by the new journal *Nonprofit Policy Forum*, among others, edited by Dennis Young and Linda Serra. Second, corporate philanthropy moves from a focus on social projects to one that emphasizes the bottom line of the corporation. In respect to this new corporate landscape, scholars explore new challenges for NPOs in regard to such issues as competition with profit enterprises and opportunities for cooperation between NPOs and profit enterprises.

These challenges affect the top management in five different fields. First, there is an increasing interest in the 'mission drift' and how or if NPOs find a balance between social mission and financial resources. Second, scholars address the different roles between the board of directors and the executive director. They focus less on normative approaches that describe the ideal governance structure than on questions of how the boards deal with conflicts and goal contradictions. Third, the current research on nonprofit strategy explores the difficulties to implement formal strategy processes within NPOs. There is an increasing interest in understanding how NPOs strategize. Fourth, more scholars explore how NPOs manage being accountable to main stakeholders. A key issue therein is to measure social impact. Fifth, and finally, the rising interest on impact measurement is why social impact assessment is an upcoming research field.

Research on Gaining Resources

Although NPOs traditionally have been able to operate effectively by focusing exclusively on their mission, many now are facing the imperative of adopting businesslike reasoning. This strengthened scholars' interest in nonprofit marketing and fund-raising. The number of contributions in these fields is immense. The discussion on enterprising NPOs leapfrogs the traditional social mission orientation of NPOs. This stream of literature focuses on NPOs that, in part, sell services or products to markets to gain money that they invest in their social services. Scholars also search for new legal forms that answer increasing financial scarcities in which they expect foundations to play a particularly critical role. Besides financial resources, the literature on volunteering focuses on human resources. Scholars explore how NPOs can gain, keep, and lead volunteers.

Because of the stronger integration of social and economic issues within most management functions, there is an upcoming discussion on hybrid NPOs. This stream of literature asks whether NPOs have to manage a single bottom line or multiple bottom lines (Anheier, 2005).

Research on Management Education

Studies confirm that executive leadership transition will be an important focus of study in the nonprofit sector over the next several years. Because of the challenges discussed thus far, the requirements of a nonprofit executive director's job gradually expand from a social focus to a more complex task at the interface of markets and civil societies (Austin et al., 2006a). Executives need to act differently to resolve or reconcile the tensions between businesslike reasoning and the social mission. These increasing job requirements lead to changes in human resources and governance structures in which executive directors play a more important role, similar to the ones in for-profit enterprises. This trend leads to a growing discussion on 'leadership deficit' and the increasing need for more skilled executives and adequate training.

As a conclusion to practitioners, these trends might differ from country to country: In some regions, NPO managers are a 'secret elite' with high social impact. In general, the tendency is to professionalize NPO management. In particular, for managers of highly professionalized NPOs, the transfer of management instruments and concepts proven to be successful in profit enterprises to NPOs and the integration of businesslike reasoning is no longer sufficient. New management concepts are needed that are suitable for executive director's specific management challenges that differ from the challenges of their colleagues in profit enterprises.

Social Entrepreneurship

Where Is SE Now?

Definitions of SE have been developed within different academic fields to refer to for profit, nonprofit, and public sector as well as hybrid organizations combining some or all the above (Peredo and McLean, 2006; Short et al., 2009). Austin et al. (2006b) defined SE "as innovative, social value creating activity that occurs within or across the nonprofit, business, or government sectors" (p. 2). Short et al. (2009) encouraged

scholars to embrace a broad definition of the concept, such as the one proposed by Mair and Marti (2006): a "process involving the innovative use and combination of resources to pursue opportunities to catalyze social change and/or address social needs" (p. 37). A unified definition has not yet emerged, making it hard for the field to establish its legitimacy. What all definitions share, however, is the social enterprises' underlying drive to create social value, rather than shareholder wealth (Austin et al., 2006a,b). For social entrepreneurs, the social mission is explicit and central; wealth is just a means to an end. Social entrepreneurs are change agents in the social sector (Dees, 2007).

One way scholars have tried to set the boundaries of the SE construct is by contrasting it with the traditional or commercial entrepreneurship. The opportunities generated by market failures, the mission of the enterprise, the mobilization of human and financial resources, and the performance measurements are fundamental distinguishing features among these two types of entrepreneurs (Austin et al., 2006b; Dees, 2007). For instance, the embedded social purpose or the nondistributive restriction on surpluses of the social enterprises limits them from tapping into the same capital markets as their commercial counterparts (Austin et al., 2006a,b). Thus, while some of them charge fees for their services, they often have to compete for donations and other types of support in the philanthropic markets (Dees, 2007). The management of human resources in the social enterprises also requires a different approach. Many rely on volunteer labor, and the economics of the enterprise often make it difficult to compensate staff as competitively as commercial initiatives (Austin et al., 2006a).

The social purpose of these enterprises makes measuring their performance a challenging task. Although commercial entrepreneurship can rely on relatively quantifiable measures, such as financial indicators or market share, to measure their performance, social change poses a greater challenge due to nonquantifiability, multicausality, temporal dimensions, and perceptive differences of the social impact generated. Measurement complications influence these enterprises' accountability and shareholder–donor relations. Other differences identified between commercial entrepreneurship and SE include the longer time it takes to achieve goals, the greater number of stakeholders involved, the absence of financial loss for stakeholders, and the nondistribution constraint of the latter (Austin et al., 2006b).

Innovation has also been acknowledged by scholars as an important feature of the social enterprises (Dees, 2007; Peredo and McLean, 2006). A significant range of activities can fall under SE, such as helping increase capacities of actors to solve their own problems, disseminating innovations to serve a widely distributed social need, and building movements to challenge the structural causes of social problems. Social entrepreneurs do not need to be inventors. They can innovate in the way they structure their core programs, in how they assemble the resources, or in the way they ensure funding for their work (Dees, 2007).

SE can occur through multiple organizational and legal forms; the particular form a social enterprise takes should be based on which format would most effectively mobilize the resources needed to address the social issue (Austin et al., 2006a). It is in part due to the heterogeneity of organizational forms that these enterprises can take that academic research on SE has been informed by for-profit entrepreneurship, social issues in management, and public and nonprofit management literature (Short et al., 2009).

At the individual level, empirical evidence of social entrepreneurs being different from its commercial counterpart is scarce. In this sense, social entrepreneurs as traditional entrepreneurs recognize and exploit opportunities to create value, employ innovation, tolerate risk, and refuse to accept limitations in available resources (Dees, 2007; Peredo and McLean, 2006). One important difference between these two types is the importance of the social entrepreneur's networking skills. These skills become fundamental for the success of the enterprise given the wide variety of stakeholders they have to cope with and the limitation of resources they often face in the philanthropic markets (Austin et al., 2006b).

Where Is SE Going?

Despite the growing attention that SE has received by scholars and practitioners in the past two decades, this academic field is considered to be in its infancy (Short et al., 2009). Research in this field has been dominated by anecdotal evidence, case studies, and conceptual papers (Mair and Marti, 2006; Short et al., 2009). For the SE field to progress, the next two decades should be characterized by unity in construct definition and by examining this construct through a variety of established theoretical lenses with clear boundary conditions (Short et al., 2009). In this line, new insights might be gained by applying a quantitative research approach more frequently. Potential avenues for future research can be explored by incorporating other disciplines in the study of SE, such as operations management, economics, marketing, finance, psychology, and accounting, which can inform the field and provide new frameworks of analysis (Short et al., 2009).

Base of the Pyramid and Inclusive Business

Where Does BoP/IB Come From?

Although it has become increasingly common to find the term 'base of the pyramid approach' (BoP, hereafter) used interchangeably with 'inclusive business' (IB), both can be traced to have different origins and to retain some specificities. The former was coined by a group of US scholars, mainly from the Universities of Michigan and Cornell, who pushed the idea that private business had a big role to play in global poverty alleviation. In essence, their message was not new: The CSR movement had been pushing that idea for decades. These intellectuals, however, innovated substantially on two accounts. First, the tone of the message changed: Although previously, the link between poverty and markets had been framed in normative terms, these authors were the first to articulate a convincing business case behind it. Second, and most important, those delivering the message were not activists, but highly credible advisors to corporate America. The result was that the concept stopped being discussed only at the company foundation or the community relations department: For the first time, it made it to the corporate boardroom.

The concept of IB, on the other hand, started to be used intensively by the mid-2000s by various practice-oriented organizations, including those that grouped large corporations – like the World Business Council for Sustainable Development, or the International Business Leaders Forum – and international development organizations – such as the *Stichting Nederlandse Vrijwilligers* (the Netherlands Development Organization, or simply SNV) or the British Department for International Development. Following their lead, various multilateral agencies – such as the United Nations Development Program, the World Bank, and the Inter-American Development Bank – quickly adopted the term and made it part of their agenda.

Where Is BoP/IB Now?

The concept of IB was defined as "one which seeks to contribute toward poverty alleviation by including lower-income communities within its value chain while not losing sight of the ultimate goal of business, which is to generate profits" (SNV & World Business Council for Sustainable Development, 2008: p. 2). This implies integrating low-income citizens as consumers, employees, producers, suppliers, distributors, retailers, and entrepreneurs. To a large extent, the IB concept stresses the role of 'anchor' companies, which open up portions of their value chain to disenfranchised groups to improve their living standards.

In its original formulation, the BoP concept was narrower, as it was presented as a neglected opportunity: a *fortune* to be captured if only companies cared enough to cater to the needs of the poor (Prahalad, 2005). Low-income citizens were seen as the new frontier, *the next 4 billion* of untapped consumers (Hammond et al., 2007). These early writings emphasized the potential of multinational corporations (MNCs) as the organizational form best placed to capitalize on the opportunity and improve the lives of the poor (Lodge, 2002), as they commanded the financial clout, global distribution channels, and brainpower needed to address the challenge. In actuality, even in those early works, the emphasis on large corporations is not absolute. Many of the cases used by Prahalad in Fortune at the BoP are not MNC: Casas Bahía was a large Brazilian Company; Voxiva a small- to medium-size enterprise (SME), and Aravind an NPO. That fact, however, was not acknowledged in the conceptual frameworks developed inductively from the experiences.

In any case, in the ensuing years, these BoP traits were softened. First, BoP authors started to recognize the critical importance of NGOs as 'unconventional partners' in hybrid value chains. Moreover, recent formulations – the so-called BoP 2.0 – expanded the definition of the concept, so as to blur most differences with IB: The emphasis on MNC is gone and the poor are seen in various roles not only as untapped consumers. "BoP ventures span sector and size, including initiatives by large multinational and domestic companies, local small and medium-scale enterprises, and business developed by nonprofit organizations and social entrepreneurs" (London and Hart, 2011: p. 10). The BoP domain is defined as those business models "specifically designed to target the poorest segments of society as consumers, producers, and entrepreneurs" (London and Hart, 2011: p. 2). Two differential shades of meaning remain, however. Although BoP authors have always stressed the need to engage the needy through ad hoc methodologies, the IB writings and practice have assumed more continuity with the status quo. Whereas the BoP success stories are all about new products, novel technologies, and hybrid business models, IB cases are about including vulnerable groups on existing value chains.

A somehow-related shade of meaning between both concepts is their relation with the wider CSR agenda. In Prahalad's (2005) seminal book, CSR is barely mentioned. In those few instances in which it is indeed brought about, the author stressed that what he proposed was something *different* from that: "This was not about philanthropy and notions of corporate social responsibility" (Prahalad, 2005: p. XIV). That emphasis was meant to highlight that there was real opportunity in this market, not just moral duty. The IB agenda, on the other hand, always remained very close to the CSR movement. This should come as no surprise, as the IB's widely cast net (encompassing consumers, employees, producers, suppliers, and distributors) overlaps nicely with the various stakeholders about whom large companies must care. In the original BoP writings, the commercial opportunity is stressed more prominently than the ethical imperative of "giving back to community," the reverse is true in the IB lexicon – although this difference has faded with time. In the last BoP writings, the social and environmental dimensions of the value created appear more prominently than the commercial opportunity. This shift may be related to the fact that for most MNC, profits at the BoP have proved somehow elusive. The evidence regarding the size and robustness of the opportunity is mixed at best. Some authors have expressed skepticism about the real commercial value of the BoP segment, pointing out that the same success stories keep up appearing over and over; some go as far as calling the BoP a 'mirage' (Karnani, 2007: p. 90). To date, few studies have tried to measure up the actual creation of economic value in BoP ventures; the microfinance industry, which has succeeded in delivering substantial financial value while at the same time transforming the lives of the poor, stands as a noteworthy exception.

Where Is BoP/IB Headed?

From the preceding paragraphs, it should be clear that one obvious trend is the convergence between the agendas and terminologies of the BoP and IB approaches. Both retain distinctive characteristics, but these seem to be losing practical relevance. Another related trend is the convergence with the so-called green agenda: Environmental concerns are increasingly prominent on BoP writings, on a par with poverty alleviation – what Hart has called 'the Great Convergence' (Hart, 2010: p. 162).

A not-so-obvious trend is the convergence between the agendas of the BoP and social enterprise. As the social enterprise literature has disengaged from specific organizational forms, accepting that SE can take place not just in nonprofits, but also in SME and even in corporations, few real distinctions separate what BoP and SE authors are studying. Finally, the social innovation approach may in the long run engulf portions of the research that currently are carried out in many of the fields of SE, CSR, IB, or BoP.

Conclusion: Trends and Implications

Whitehead suggested the last thing to be discovered by any science is what the science is really about, and this seems to be true in this case. The concept of social business is in its infancy, but the field has been growing rapidly in multiple interrelated dimensions. Practical implications and managerial initiatives have been strong in parallel with conceptual development. A managerial core on CSR has matured into distinct research areas. Social business, as economic activities for social value creation, will become a core concept integrating the multiple avenues of research and practice. At least four directions focus future development of the field: the consolidation of good management, international regulations, blurring borders among sectors, and the transformation of capitalism.

Social business management is being consolidated by trends to certifications, such as ISO, emerging codes of ethics and malpractice for the managerial profession, interactive learning between sectors, development of techniques and best practices to reduce uncertainties of business and society, and theoretical development of management techniques. Marketing, human resources, informatics, finance, operations, and strategy, among other subfields of management, will become more sophisticated, integrating concerns of the stakeholders. For example, public relations will no longer be just pushing press releases and propaganda, but rather listening to the public and to all stakeholders of a company. Organizations of the private, public, and third sectors will have higher standards and accountability when dealing with employees, consumers, suppliers, shareholders (economic sustainability), governments, communities, and the environment.

The trend of international regulations will be particularly strong on environmental issues (i.e., organic agriculture), human rights, labor fairness, the conduct of war, and governance regulations. Multilateral international organizations will have more control and will make international regulations and agreements more enforceable. Probably ISO 26000 will be certifiable, as the other norms of ISO now are. That way the concerns of social business will be widespread.

Foundations, NGOs, cooperatives, and NPOs normally will be required to be efficient, generate their own income, and evaluate their real social impact. Public sector organizations will be accountable on the real impact of policies. Private companies as well as public organizations and social enterprises will be required to be economically sustainable, achieve social value, and contribute to environmental sustainability, the triple bottom line. Some may be called 'fourth sector' or 'hybrid organizations'; strategic alliances among sectors may increase and cross-learnings will become highly valuable. The trend to the blurring of sectors will mean a convergence of management and a development of management as a professional activity.

The emergence of the social sciences in the nineteenth century witnessed a preoccupation with the decrease of solidarity in capitalist society, or at least a change in the nature of the institutional ties that hold society together. Probably the evolution of capitalism implies changing its very nature. A most successful leader of social business predicts a blooming of social capitalism, a second type of private economic activity oriented to social ends (Yunus, 2008). It may be quite a ways away, but the consolidation of important initiatives of new philanthropy, volunteer work and nonprofits, social investments, IB, and SE as we have seen in this century may result in changes of 'capitalism' as understood by Adam Smith.

This article is a revision of the previous edition article by R.W. Jackman, volume 21, pp. 14216–14219, © 2001, Elsevier Ltd.

Abstract

The French sociologist Pierre Bordieu defines social capital as "the sum of resources, actual or virtual, that accrue to an individual or group by virtue of possessing a durable network of more or less institutional relationships of mutual acquaintance and recognition." There are different definitions of social capital, but his definition captures the key idea that it is a resource which individuals can utilize to further their goals, but which resides at the level of the community. It is created and fostered by relationships between individuals of a voluntary and nonfinancial nature. This article reviews varying definitions of social capital before going on to examine its origins, which can be traced back to both microlevel or individual, and macrolevel or community-based social processes. Finally, the article examines the effects of social capital on society and policy-making, reviewing the evidence that it has benign effects in relation to economic prosperity, educational attainment, health and welfare, crime reduction, and subjective well-being in communities where it is abundant.

Introduction

The concept of social capital has its antecedents in a long tradition of studying the role of communities in human society, which goes back to Greek philosophers such as Plato and Aristotle. Many classic theorists such as Adam Smith, Alexis de Tocqueville, and Emile Durkheim have examined ideas relevant to understanding what is now known as social capital (Bowles and Gintis, 2002). The concept has gained prominence in recent years from the work of three notable theorists: Pierre Bordieu (1986), James Coleman (1988), and Robert Putnam (1993). At its core, social capital emphasizes the importance of community ties between individuals in facilitating and enabling collective action to take place. For Coleman, social capital permits society to do things that it otherwise could not do, and though it is utilized by individuals it originates in relationships between people in society. Coleman wrote: "Like other forms of capital, social capital is productive, making possible the achievement of certain ends that would not be attainable in its absence" (Coleman, 1990: 302).

He illustrated the effectiveness of social capital with the example of the New York wholesale diamond market. In this market it is common for participants to hand over bags of diamonds to each other to permit closer examination, without any insurance or formal contracts. This market is based on trust and it works very effectively. This is largely because the community of traders is dominated by orthodox Jews, who share the same religious beliefs, live in the same highly integrated community, and trust each other. Someone who takes advantage of this trust and cheats risks being ostracized not only by other traders but by the community they live in.

The French sociologist Pierre Bordieu provided as succinct a definition of social capital as anyone. He writes:

> Social capital is the sum of resources, actual or virtual, that accrue to an individual or group by virtue of possessing a durable network of more or less institutional relationships of mutual acquaintance and recognition.
>
> Bordieu and Wacquant, 1992: 119

There is a lively debate about the meaning of social capital with some writers emphasizing its importance to the individual as a resource which they can use to promote their private interests (Lin, 2001), while others emphasize the importance of trust, shared norms, and values in the wider society (Fukuyama, 1995), and yet others like Bordieu highlight the importance of connections between individuals in social networks. The study of social capital was given a big impetus by the publication of *Making Democracy Work* (1993) by Robert Putnam, who examined the effectiveness of democracy in the Italian regions. He explained the large social, political, and economic differences between these regions in terms of their different endowments of social capital.

Putnam found that in regions like Emilia-Romagna in northern Italy, people were sociable, joined voluntary groups, and took part in a wide variety of activities, both formal and informal, which put them in close contact with their fellow citizens. He argued that this built a reservoir of social capital and a willingness to trust others, particularly strangers. In contrast, in the southern region of Calabria civic life was not conducive to building social capital since there were fewer voluntary associations, less social activity, and lower levels of trust. In Emilia-Romagna, citizens developed strong 'norms of reciprocity' and this had a benign effect on many aspects of life in the region including promoting economic prosperity, improving health, assisting educational improvements, encouraging political participation, and enhancing subjective well-being. In this part of Italy people came to expect fair dealing, both from their fellow citizens and also from the regional government. By contrast, in Calabria civic life was not conducive to building social capital, since individuals were not inclined to trust their fellow citizens or the government and as a consequence associational life was neglected. Norms of reciprocity and trust were relatively weak and government did not work very well.

Putnam's argument has its roots in Alexis de Tocqueville's *Democracy in America* (1990(original 1840)) which argued that interpersonal trust and associational life are linked in a virtuous circle, so that as people mix with others in an

informal, voluntary setting, they come to know and trust each other, and this in turn promotes more voluntary activity and civic engagement. As this happens the feelings of trust begin to extend to people beyond the individual's immediate family and circle of acquaintances. These interactions produce what the economists call 'externalities,' which arise when transactions have external effects on others. In this case cooperative behavior spills over into the wider society. Because they know and trust their fellow citizens they are more likely to trust and to help strangers. As social capital develops, society works more efficiently by reducing the transaction and policing costs associated with widespread levels of mistrust between individuals. Societies poor in social capital display only weak associational ties and exhibit limited mutual trust, and as a consequence, they fare worse and work less efficiently than their more fortunate neighbors.

Putnam (2000) drew attention to the 'dark side' of social capital, making the point that the consequences of social capital are not all benign. He makes the distinction between 'bridging' and 'bonding' social capital, the former referring to networks which link diverse communities together, and the latter which keeps them apart. He cites the civil rights movement in the United States and ecumenical religious organizations as examples of the former, while ethnic fraternal groups and exclusive country clubs are examples of the latter. A contemporary example of this would be Northern Ireland which has a lot of social capital in the sense of strong local communities, but they are divided by religious and political differences with Protestant communities having very limited contact with Catholic communities.

Another distinction which has been made in the literature relates to 'linking' social capital which describes connections between individuals in a hierarchical setting with unequal levels of power. Bridging or bonding social capital refers to relationships between individuals at a horizontal level, or between people who are more or less on an equal footing. Linking social capital is very relevant for understanding how people see their government or their superiors in any hierarchical organization.

The social capital idea has been subject to considerable critical scrutiny, both theoretical and empirical (Tarrow, 1996; Claibourn and Martin, 2000; Milner, 2002; Halpern, 2005). One issue concerns the relationship between social capital and financial capital. In the case of financial capital it is depleted by use, so that if an individual spends their savings they will not then be available for investment. However, the same is not true for social capital which is depleted by a lack of use. In this case if individuals cease to take advantage of social capital by working together in communities, then it will depreciate over time. The term 'use it or lose it' very much applies to social capital in a way which is not true of financial resources.

Measuring Social Capital

Just as there are disagreements about the definition of social capital there are disagreements about its measurement (Portes, 1998; Adler and Kwon, 2002). For many researchers the essence of social capital is captured by measures of interpersonal trust (Fukuyama, 1995; Brehm and Rahn, 1997; Pattie et al., 2004). For others it is best measured by the number of voluntary organizations which exist in society and which people are prepared to join (Paldam and Svendsen, 2000). Yet others think that the primary focus should be on measuring the social networks in society, particularly those that facilitate economic prosperity arising from 'weak ties' (Granovetter, 1973; Lin and Erickson, 2008). A number of researchers, including Putnam himself, combine all three measures and define social capital in terms of the sum of formal and informal networks together with levels of interpersonal trust in society (Putnam, 1993; Cote and Healy, 2001).

However social capital is measured, there are wide variations in its incidence both within societies and across countries. This can be illustrated with the assistance of a question asked in the World Values surveys (see http://www.worldvaluessurvey.org). These surveys are aimed at measuring the values, attitudes, and social norms of individuals in a large number of countries. The aim is to understand variations in culture, morality, voluntary activities, religiosity, and a variety of other measures across the world (see Inglehart, 1990). The question is *Generally speaking, would you say that most people can be trusted or that you need to be very careful in dealing with people?* The 2010–2012 survey showed that only about 24% of respondents in 51 countries agreed that people could be trusted, while 73% felt that they had to be careful in dealing with other people. **Figure 1** shows the percentages of people who trust, analyzed countrywise.

Figure 1 shows that willingness to trust others varied from 3% in the Philippines to 67% in the Netherlands. Even taking into account the difficulties of comparing very diverse sets of people using different languages and having different cultures this is an amazingly large variation. In some countries like Colombia, pretty much no one trusts anyone else, whereas in other countries like Sweden levels of trust are very high. Insofar as this question captures social capital, then it is extremely diverse.

A glance at **Figure 1** suggests that there are several important correlates of social capital. It appears to be more abundant in Western-style developed democracies with relatively high standards of living, and much less so in poor, developing countries with nondemocratic governments. However, trust is clearly not just a function of income or wealth, since a relatively poor country like Kazakhstan is well above a number of more affluent countries like Spain and Taiwan on the scale. Similarly, despite the heavy focus of research on social capital on the United States, that country is not in the highest trust group which appears to be dominated by other mature democracies such as Australia, Sweden, and the Netherlands. **Figure 1** raises intriguing questions about the sources and origins of social capital, a topic we consider next.

The Origins of Social Capital

There is great diversity in accounts of the origins of social capital with microlevel and macrolevel explanations competing with each other. At the micro, or the level of individuals, some neuroscientists have argued that humans are hardwired to trust each other and to exhibit altruism in their relationships (Grimes, 2003). At the other end of the scale, it

Figure 1 Percentages who trust others in fifty-one countries, 2010–2012. Source: World Values Dataset, 2010–2012.

has been argued the origins of social capital lie in long-standing and sweeping macrolevel historical forces, a position taken by Putnam (1993) in his early work.

If we consider microlevel explanations first, then there is a lot of research in behavioral economics which shows that individuals are not the self-centered utility maximizing entities of traditional economic theory (Camerer, 2003). This can be illustrated by game theory, which is the study of rational decision-making in situations of conflict and cooperation (see Rapoport, 1970). The ultimatum game involves two participants, one of whom makes an offer to the other to divide up pot of money between them (Guth et al., 1982). If the latter accepts the division, then they share out the money and the game ends; if not, then neither of them gets anything. Traditional economic logic would suggest that the proposer should take as much of the money as possible, subject only to the responder being given something. Equally, the latter should accept any division of the money, which gives them a positive amount, on the grounds that something is better than nothing.

However, this is not what happens in a laboratory setting. In numerous experiments proposers offer an average of about 40% of the money with many offering half. Similarly, responders reject offers involving less than 20% of the money about half of the time (Camerer, 2003: 43). The assumption that players maximize their own returns with minimal concessions to other people is clearly falsified by these experiments. This is because issues of fairness and justice, which are hardwired into the great majority of individuals, play an important role in decision-making. Individuals are altruistic and consider the welfare of others.

Trust games get even closer to the idea of social capital than ultimatum games. These are a variant of ultimatum games in which an 'investor' decides how much of a given pot of money should be invested or kept. The invested portion of the money produces a return and this is then divided up by a 'trustee' between the two of them (Berg et al., 1995). The investor has to make a risky decision at the beginning knowing that by investing the money she or he may not get any return if the trustee keeps the proceeds to themselves. Patterns of altruistic behavior are clearly apparent in these games, with completely selfish investors or trustees being quite rare phenomena. Trust occurs and is rewarded, although there are variations in the levels of generosity of participants (Camerer, 2003: 85–86).

These laboratory experiments show that narrow, selfish behavior is not the norm as far as society is concerned. Trust and trustworthiness is hardwired into the human brain and it affects behavior generally, making it an important feature of human society. Having made this point, however, it is readily apparent in **Figure 1** that there are large variations in trust across different types of society, although it is important to remember that trust in response to the simple question in the World Values surveys can be bonding rather than bridging. The experiments suggest that almost all humans trust but trusting strangers, a key feature of social capital, is less common, particularly in some societies. This suggests that the context in which individuals live is very important for understanding the origins of social capital.

At a more macrolevel of analysis, considerable work has been done to investigate how cooperation between individuals evolves over time. This work utilizes the prisoner's dilemma game to model cooperation (Rapoport, 1970). This is one of the best known games in the literature and gets its name from the story used to illustrate the decision problem of the actors involved. The story is that two suspects are arrested on suspicion of committing a crime, but the prosecutor can not convict them without a confession from at least one of them. They are separated and interrogated with the aim of getting one of them to confess and give evidence against the other. If neither confesses they both get a short jail sentence based on a lesser charge which can be proved without a confession. However, if one confesses and agrees to give evidence against the other, he gets a reduced sentence while his companion gets a severe

sentence. If both confess and offer to testify against each other then both get a heavier sentence than they would have if neither had confessed. This is the prisoner's dilemma.

If the game is played only once then the optimal strategy for both prisoners is to confess, on the grounds that they can not trust each other. Whatever their companion does they are better off confessing than taking the risk that they will be the one not to confess. This produces a joint outcome which is worse than the one which would occur if they cooperated with each other and did not confess. This game has been used in a variety of settings, particularly as a model for understanding the 'tragedy of the commons' (Hardin, 1968), or the depletion of the world's finite resources such as the Amazon rainforest and fish stocks in the oceans.

If this game is played repeatedly over time then the prisoner's can learn to trust each other and avoid the heavier sentences by cooperating in a series of plays. Analytical or computable solutions to the problem of how cooperation develops in the sequential game are difficult to find because of the complexities of the problem. With this in mind, the political scientist Robert Axelrod (1984) organized a computer tournament between academic colleagues working in the areas of game theory and decision-making in order to try to find out which strategy is most likely to elicit cooperation in the sequential game.

The winner of this tournament was the relatively simple strategy called 'Tit for Tat,' which involves cooperating on the first move and continuing to do so if your companion reciprocates. However, if he defects by confessing then the individual should immediately retaliate by confessing on the next round of the game. If the companion subsequently reverts to cooperation, then the individual should again reciprocate on the next round. Since cooperation is rewarded and defection is punished then the likelihood of developing cooperative strategies over time is greatly increased. The strategy works because it is simple and easy to understand; it retaliates against bad behavior, but is also forgiving in the sense that it rewards a resumption of cooperation.

This research has generated a lot of experimental work on the problem of cooperation (Axelrod, 1997; Ridley, 1997; McCulloch, 2008) and it is valuable in highlighting the circumstances in which social capital can develop. It is more likely to develop in small communities in which individuals tend to know each other and interact frequently rather than in isolated hunter–gatherer societies where interactions are infrequent outside of the family and tribe. It helps to have sanctions against noncooperative behavior, but they should not be too inflexible and draconian. If sanctions are very large and inflexible they do not encourage a resumption of cooperation if it breaks down at some point, and noncooperative behavior is likely to become entrenched. One implication of this is that social capital is less likely to emerge in large cities where people are anonymous and frequently interact with strangers on a one-off basis. There is convincing evidence to support this hypothesis (Oliver, 2001).

Sociologists have drawn attention to the importance of the family and in the early socialization experiences of individuals in creating social capital. Bowlby (1988) for example, argues that infants benefit greatly from the relationship with their primary caregiver, most commonly the mother and a secure bonding between infant and mother will provide the basis for trust and cooperation in later life. Family breakup involving divorce tends to reduce generalized trust among children (Hall, 1999), the loss of one parent reducing emotional support and also access to wider social networks (Jonsson and Gahler, 1997).

Of course the family is embedded in a wider society, and so weak or fragmented relationships between families in communities will very likely reduce social capital. In a famous study of a village in southern Italy, Edward Banfield (1958) showed that societal relationships were characterized by 'amoral familism' or a persistent failure of individuals to cooperate with others outside of their immediate family. He attributed this in part to high levels of mortality and a fragmented system of land tenure which inhibited collective action. Other factors such as religion, national identities, and individual personality characteristics also influence the creation of social capital (Whiteley, 1999).

While stressing the importance of networks of voluntary associations in the creation of social capital, Putnam (1993) controversially argued that the origins of the large differences in social capital across the Italian regions lay in the medieval history of Italy. In 1231 Frederick II, who had established dominion over southern Italy, established a new constitution which cemented his hold over the region and entrenched an autocratic state (Putnam, 1993: 123). In contrast in the northern city-states such as Florence, Venice, Bologna, and Milan fledgling semidemocratic constitutions emerged, which involved significant citizen participation in government (Putnam, 1993: 124). These historical circumstances laid down different path dependencies in these regions and promoted cooperation between citizens in the north, and alienation between them in the south. This interpretation of what happened in medieval Italy has been challenged (Ferrangina, 2013), but it does draw attention to the importance of the social and historical context in explaining how social capital develops over time.

One of the criticisms of Putnam's analysis was that it played down the importance of inequality in influencing social capital. It has long been recognized that the middle class have larger and more diverse social networks than the working class, and the evidence suggests that the well-off are usually more trusting and more likely to volunteer than the poor (Goldthorpe et al., 1987; Hall, 1999). Edwards and Foley (1998) have drawn attention to the point that networks are only useful to the extent that they provide resources that individuals can utilize. Variations in power and resources in different types of network produce huge differences in the effectiveness of social capital, and **Figure 1** suggests that standards of living clearly influence social capital, and so this is an important point. As Halpern puts it:

> If you are a fairly well-connected middle-class person, it might be that the numerical size of your network may not be all that different from that of Bill Gates, Richard Branson, Prince Al Waleed bin Talal or whoever… But if we instead look at the resources that a billionaires network provides access to compared to our own, we would see a world of difference.
>
> 2005: 23

Overall, it is clear that both microlevel and macrolevel factors are at work in influencing the emergence of social

capital. Individual psychological predispositions play an important role, as does the family but they can be fostered or inhibited by the communities in which people live and by the governments in those societies. On a broader level they are influenced by relationships between the state and individuals. Governance influences social capital, just as social capital influences governance. At the same time many of the effects of social capital as far as policies are concerned are influenced by levels of inequality in society (Wilkinson and Pickett, 2011); so there is a clear link between inequality and social capital.

One of the reasons why the concept of social capital has attracted so much attention is because of the benign benefits which appear to be associated with it. We examine these next.

The Effects of Social Capital

Social capital appears to have major consequences for society. Research suggests that societies where levels of trust and voluntary activity are high tend to perform better on a variety of important social and economic indicators than societies where trust is low and voluntary activity is lacking (Knack and Keefer, 1997; Inglehart, 1999; Whiteley, 2000; Knack, 2002). Putnam (2000) shows that social capital in America delivers many benefits to localities such as greater economic prosperity, better health outcomes, reduced crime, improved education, and even higher levels of life satisfaction or subjective well-being.

To illustrate how these benefits can occur, it is instructive to take the example of social capital and economic growth. It is quite clear that interpersonal trust has a positive impact on economic growth in a variety of countries, controlling for other important determinants of growth (Whiteley, 2000). This works in a number of different ways. Firstly, widespread trust reduces the transaction costs of doing business; there is less need for complex contracts and expensive lawyers to draw up and enforce such contracts if individuals can trust each other. The example of the diamond market in New York is instructive in that regard. Secondly, if people are more trustworthy then crimes such as fraud and theft are likely to be less of a problem and that in turn reduces the costs of doing business. As well as lower costs of crime, social capital also reduces the costs associated with policing and law enforcement.

A third aspect of the effects of social capital is that principal–agent problems are likely to be lower in societies with high levels of social capital. These occur when an employer (the principal) has to trust an employee (the agent) to deliver a service without fully being able to supervise the quality of their work. In this situation, the agent has an incentive to shirk on the delivery of the service, which in turn lowers overall productivity and restricts growth. Finally, in high-trust societies individuals can afford to take more risks when they innovate, by investing in projects that might pay off but which are potentially money losers. Clearly, low-trust societies are likely to be more risk-averse than high-trust societies and this can hamper innovation and economic performance. Overall, we can see that there are many ways in which social capital can influence economic growth.

There is evidence of a decline in social capital in the United States since the 1960s, and after considering various alternatives Putnam (2000) claimed that television was responsible for this development. A similar argument might be developed about the Internet, given that it is now ubiquitous in Western societies. Television usage in the 1950s and 1960s and Internet usage in the 1990s and 2000s became very widespread. Both tend to isolate people in front of their screens, and reduce the time available for interacting and networking which are the mechanisms that promote social capital. Hence the rise of television and the Internet may be weakening social capital. Not surprisingly, though, these claims are controversial. Norris (1996) took issue with the argument that television has reduced social capital, and there is no evidence to suggest that Internet usage has limited activism in voluntary organizations such as political parties (Whiteley, 2011).

One early finding was that while social capital has been declining in the United States, it does not seem to have declined much in Britain (Hall, 1999). However, this conclusion was premature, since it was based on evidence available only up to the 1990s. Subsequent research has shown that social capital has declined in Britain in a similar way to the United States (Grenier and Wright, 2001). An illustration of this can be found in the World Values surveys conducted in 1981 and again in 2005 in Britain. In the 1981 survey some 43% of Britons thought that most people can be trusted, but by a quarter of a century later, this figure had declined to 30% (Whiteley, 2012: 85). A similar point can be made about voluntary associations in Britain. Church membership, party membership, the Women's Institute, and above all trade unions have all been declining in Britain over time (Whiteley, 2012: 83). While large charitable organizations such as the National Trust continue to attract members, these are largely 'cheque book' participants, who pay their dues but do not get actively involved (Jordan and Maloney, 1997).

Another finding relates to the link between local government and social capital in Britain. While spending on local services does not appear to be influenced by social capital, the policy outcomes derived from such services are affected. In the case of education, for example, which is the biggest item in the budget for English and Welsh local authorities, the best pupil performances in GCSE are found in areas with high levels of political participation and associational activity (Pattie et al., 2004: 189–223). Other case studies of real estate development and urban management schemes in the United States have shown that social capital significantly improves the quality of policy delivery (Saegert and Winkel, 1998; Glaeser and Sacerdote, 2000).

These findings all suggest that social capital is an asset to effective governance and policy-making, but its relationship to political participation is more ambiguous. Putnam (2000: 31–64) produced a lot of evidence to support the idea that social capital and political participation have both declined at the same time in the United States. But there are indirect links between social capital and political participation. The civic voluntarism model of political participation has long established that there is a correlation between social status, personal affluence, and education on the one hand and indicators of social capital such as trust and voluntary activity on the other (Parry et al., 1992; Verba et al., 1995). This model shows clearly that social status and affluence are determinants of political participation, which establishes an indirect link between social capital and participation. Translated to the level of the

community, this implies that greater affluence produces higher levels of social capital which in turn produces higher levels of civic involvement.

However there is an ambiguity in this relationship. Eric Oliver (2001) points out that social capital is not the same as affluence and that participation varies systematically across different communities in the United States in a way which is unrelated to their standards of living. In his analysis political participation is greater in economically mixed communities than in either very poor or in very rich communities, even when controlling for individual-level factors such as the survey respondent's income. A similar point can be made about racial mixed communities which tend to have higher rates of participation than homogenous white or black communities.

His argument is that individuals are more likely to have to protect their interests by getting involved in 'mixed' rather than in homogenous communities. Politics in diverse communities involve a battle between individuals with rather different interests, whereas in homogeneous communities the residents tend to have similar interests. If an individual has roughly the same interests as the rest of the people in their community, they can safely leave it to others to make decisions in the knowledge that they are likely to get the mix of taxes and spending they prefer. In this situation the risks of nonparticipation and the potential gains from participation are not that great. However, this is not the case in heterogeneous communities where the political process can produce large differences in policy outcomes. If individuals do not get involved in such communities they may well end up with policies which they regard as highly undesirable. This argument is a challenge to social capital theory, since it is often the most homogeneous communities which have the most social capital.

Conclusion – Where Does Social Capital Go from Here?

The research on social capital is rich and diverse and it contains a number of controversies which are to be expected in relation to such a broad and important concept. As we have seen there are microlevel foundations to social capital and it can be promoted or inhibited by the communities in which people find themselves, but also by broad historical events which can change the trajectories of different societies. It is no surprise for example to see in Figure 1 that ex-communist countries such as Slovenia, Poland, and Russia have less social capital than Western democracies such as the Netherlands and Sweden. Communism with its pervasive surveillance state and refusal to permit independent organizations undoubtedly weakened social capital. Also there is a good deal of evidence in the figure that authoritarian societies have less social capital than democratic societies, a point made by Putnam.

The key challenge for the social capital research agenda is to map out clearly where it is declining and where it is not, as a preliminary exercise to understanding the dynamics of social capital over time. In the past high-quality comparative data on social capital was hard to come by, but international research initiatives such as the European Social Survey, the International Social Survey Programme, and the World Values Surveys have made the task of mapping social capital in diverse societies much easier. On the other hand comparative longitudinal data are still hard to come by, but it is essential to have this if the long-term effects are to be better understood.

Social Capital in Organizations

Abstract

Social capital represents the set of interpersonal relationships which provide resources that create value for individuals in organizations. The most studied forms of social capital describe social relationships in terms of the tie characteristics and the position an individual occupies in the network structure of relationships. Social capital provides resources such as information, control, trust, and support. It affects attitudinal and behavioral outcomes and it is affected by individual dispositions and contextual factors. Social capital can be used to study intra-organizational and inter-organizational relationships.

Social capital refers to the set of interpersonal relationships which create value for individuals in organizations. The concept has been imported to organizational studies from sociology. Sociologists have always been interested in observing how individuals cluster in social groups and they began acknowledging that social relations may be beneficial for the individuals who are embedded in them. The core intuition behind social capital is that social relationships provide resources which can enable individuals to attain desired outcomes. While sociologists focused on studying a wide array of social relationships involving family, friendship, or affiliation to political and social groups, organizational theorists began examining social relationships at work. Scholars in social networks have elaborated on the concept of social capital to specify its forms and identify the way in which they affect individual outcomes. A fundamental contribution provided by social network theorists highlighted that social capital is not merely related to the number of dyadic relationships between pairs of individuals, but it relates to the way in which relationships combine in structural patterns.

There are different forms to specify social capital and different ways in which social capital creates value for individuals. In order to shed light on the concept and implications of social capital, the present article is structured as follows. The first part reviews and discusses the different definitions of social capital. The second part describes the forms of social capital and illustrates which kind of social relations are likely to create value for individuals. The third part explains how social relations create value, describing the resources that social relations give access to. The fourth part reviews the core beneficial outcomes stemming from the exploitation of the resources provided by social relations. The fifth part focuses on the sources of social capital. The last part extends the arguments of social capital to the relationships among organizations.

The Concept of Social Capital

Adler and Kwon (2002) provide the core intuition behind social capital: whereas market relationships are characterized by economic exchanges in which individuals trade goods or services for money, interpersonal relationships are characterized by social exchanges in which individuals exchange favors. Anytime an individual grants a favor to another individual, he or she will receive a 'credit' or goodwill which can be used as a resource to facilitate the attainment of personal outcomes in the future. Social capital theory suggests that interpersonal relations create value for individuals as they provide resources which can be used for the achieving desired outcomes. Yet, although the core argument of social capital is clear and scholars seem to have converging opinions about it, what exactly does the concept of social capital capture? Does it reflect the social relations, their value, or the resources? Scholars have not reached agreement on that, and several conceptualizations have been used to characterize social capital.

In the first conceptualization, social capital in organizations equals social relations, generally described as the structure of social networks. According to Galunic et al. (2012: p. 1215) "social capital is primarily about the relationships that actors maintain, characterized in terms of such features as number, strength, and density." Burt (1992: p. 9) identifies social capital as "friends, colleagues, and more general contacts through whom you receive opportunities to use your financial and human capital." Nahapiet and Ghoshal (1998) acknowledge that one of the most popular conceptualizations of social capital focuses only on the structure of network relationships developed in organizations.

In the second conceptualization, social networks are exogenous to the definition of social capital. Social capital and social networks are two independent but causally related concepts. More specifically, social networks are said to be the cause of social capital. In Inkpen and Tsang (2005) the authors specify that social capital originates from social networks. Gulati and Gargiulo (1999) specify that social networks create social capital and identify social capital as the assets tied to the manager's network. Burt (2001) explicitly mentions that network structures create social capital. Hence, if social networks create social capital, they are exogenous to its definition and social capital is conceptualized as the result of social networks. More specifically, social capital is identified with the resources which are provided by social networks. Adler and Kwon (2002: p. 23) argue that "social capital is the goodwill available to individuals and groups. Its source lies in the structure and content of the actor's social relations. Its effects flow from the information, influence, and solidarity it makes available to the actor." Bourdieu (1985: p. 248) defines social capital as "the aggregate of the actual or potential resources which are linked to possession of a durable network of more or

less institutionalized relationships of mutual acquaintance or recognition."

In the third conceptualization, social capital refers to both social networks and the resources provided with them. In the definition of social capital we find two elements: the social networks and the resources. Here social networks are no longer exogenous to the definition of social capital. From Nahapiet and Ghoshal (1998: p. 243), we read that social capital is defined as "the sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit. Social capital thus comprises both the network and the assets that may be mobilized through that network." We can read from Boxman et al. (1991: p. 52) that social capital is "the number of people who can be expected to provide support and the resources those people have at their disposal."

Although authors seem to disagree significantly on the theoretical conceptualization of social capital, when it comes to its empirical operationalization we find far more convergence. No matter how scholars define social capital, they most often tend to measure it by capturing the interpersonal relationships that individuals develop in organizations. The resources provided by social capital are mostly assumed to represent the explanatory mechanisms which relate interpersonal relationships to individual outcomes of interest. Yet, not all interpersonal relationships represent social capital. Coleman (1990: p. 302) specifies that "social capital is defined by its function. It is not a single entity, but a variety of different entities having two characteristics' in common: They all consist of some aspect of social structure, and they facilitate certain actions of individuals who are within the structure." As both Burt (1992) and Coleman (1990) acknowledge, social capital is therefore composed of the specific set of interpersonal relationships which create value for individuals in organizations.

The Forms of Social Capital

Which interpersonal relationships are likely to create value for individuals in organizations? Scholars have not reached consensus on which relationships constitute social capital and have developed conflicting arguments highlighting the benefits of different forms of social relations. We can identify three main levels that scholars have considered when studying social capital. The first is the tie level, at which social relationships are described by observing the characteristics of ties linking individuals. A popular way to study the characteristics of ties is through their strength, measured as the intensity or frequency of interactions among individuals. Granovetter (1973) theorized that weak ties tend to be particularly advantageous for individuals and highlighted the mechanisms through which they give access to opportunities. Yet, strong ties could be beneficial as well given that a strong bond between individuals facilitates sharing privileged experiences and information which would not be normally shared through weak ties (Altman and Taylor, 1973).

The second level is the local structure level, which identifies the relationships that an ego (the focal individual) has with his or her alters (the direct connections) and the relationships that these alters have among each other. Scholars are involved in an ongoing debate regarding which type of local structure is more beneficial to individuals. Burt (1992), on one side, argues that brokerage, in which the ego bridges 'structural holes' among unconnected alters, is beneficial to individuals. Coleman (1990), on the other side, argues that closure, in which an ego is tied to alters who are connected to each other, can be more advantageous. Scholars have embraced different positions elaborating alternative theoretical arguments on which type of local structure can create value for individuals and hence qualifies as social capital.

The third level is the global structure level, which captures the position that an individual occupies in the whole network of relationships in the organization. Network centrality has been used as prominent concept and it identifies the extent to which individuals occupy a central position in the network. There are different types of centrality. Betweenness centrality describes the extent to which individuals fall 'in between' others and captures the degree to which shortest paths connecting any pair of individuals in the network pass through the focal actor. Closeness centrality describes the extent to which an individual is 'close' to all others and observes the average path distance between the focal actor and all other actors in the network. Eigenvector centrality describes the extent to which individuals are tied to 'popular' alters, who have many connections. While there is active debate regarding which tie characteristics and which local structure allow more advantages, there is more convergence on the idea that a central position allows better access to resources than a peripheral position.

The Benefits of Social Capital

If we define social capital as the interpersonal relationships which create value for individuals through the provision of resources, it becomes important to identify which resources are provided by which form of social capital. This section identifies the most commonly referenced resources provided by social capital. The first and most prominent resource provided is information. Several forms of social capital provide informational advantages. At the tie level, weak ties are expected to be efficient in transferring information while strong ties are expected to be effective in transferring tacit and complex information (Hansen, 1999). At the local structure level, brokerage positions rich in structural holes are supposed to provide nonredundant information (Burt, 1992). While individuals in a closed structure will be exposed to the same information which redundantly circulates inside the network, individuals in an open structure will be more likely to gain timely access to diverse information. Closed structures with dense relationships are also supposed to give some informational advantages as circulation of information within a closed network tends to be particularly efficient (Coleman, 1990). Last, at the global structure level, network centrality leads to informational advantages as individuals can benefit from being positioned in the midst of multiples flows of information (Mehra et al., 2001).

A second resource provided by social capital is control. Control is typically provided at the local structure by brokerage positions, in which the individual can beneficially exploit the lack of connection between alters (Burt, 1992). Given that the alters cannot exchange information about the broker,

the broker benefits from a positional advantage which makes alters dependent on him or her, allowing negotiation leverage. Ideally, control over others can be exercised also by central positions in the global network as centrality could create conditions of dependence on the central individual while allowing that person to be relatively independent.

A third resource provided by social capital is trust. Trust is mostly provided at the local structure by closure (Coleman, 1990). While brokerage allows the ego to exercise control on the alters without being controlled by them, closure allows alters to exercise control on each other, hence discouraging opportunistic behaviors and facilitating the conditions for the emergence of trust in the network. Trust could also be provided at the tie level as strong relationships entail intimacy and generate the conditions for the development of trust among partners (Altman and Taylor, 1973).

A fourth resource provided by social capital is support. Social relationships can provide instrumental support through referrals. The social network of an individual does not only give him or her information, but it also diffuses information about the individual to all other persons in the network. That information can grant access to opportunities or help to build reputation within the organization. Burt (1992) acknowledges that individuals in brokerage positions are more likely to benefit from referrals. Centrality can also be beneficial in gaining support and in establishing positive attributions and beneficial reputation in the organization (Balkundi et al., 2011). Finally, social capital can provide emotional support as relationships help overcome situations of distress or transfer positive emotions through contagion dynamics (Totterdell et al., 2004). Such support could be provided by strong ties (Altman and Taylor, 1973) as well as by network closure at the local level (Totterdell et al., 2004).

The Outcomes of Social Capital

The resources provided by social capital are likely to be exploited by individuals in order to attain desired outcomes in organizations. Specifying the outcomes the individuals are capable to attain through their interpersonal relationships is fundamental to establishing whether these relationships constitute social capital or not. Social capital has been associated with attitudinal outcomes (Totterdell et al., 2004). Individuals have an innate need for social interaction and social relationships at work can provide the resources to satisfy their social needs and develop positive attitudes toward the job – such as job satisfaction – or toward the organization – such as organizational commitment. The resources of emotional support and trust provided by social capital could be particularly relevant for the prediction of attitudinal outcomes. However, the opportunity to exercise control also generates positive attitudinal responses on individuals. Tie characteristics, local structure and global structure can all exercise predictive effects on the individual's attitudes and more specifically on positive or negative affectivity (Totterdell et al., 2004).

Social capital has also been associated with behavioral outcomes and more specifically with individual performance (Mehra et al., 2001). Social capital could directly or indirectly affect individual performance. It could indirectly affect individual performance through the mediation of positive attitudes: social capital triggers positive attitudes, which fuel motivation and make individuals perform better. Social capital could also directly affect performance through the resources it gives access to. All the resources identified in the previous section are directly likely to explain the relationship between social capital and individual performance. All the forms of social capital identified above have been studied in relation to performance, employing alternative theoretical positions. It is important to acknowledge that social capital can affect different forms of performance. The resources of information, control, trust, or support could allow individuals to better achieve in-role performance, in which they can effectively execute their assigned tasks. The resources of social capital could also allow individuals to better achieve extra-role performance, in which they perform activities that create value for the organization but are not formally expected to be performed. For example, the social capital of individuals could affect their organizational citizenship behaviors (Bowler and Brass, 2006). Another type of behavioral dimension studied in social capital research is creative performance, given that the informational advantages of social relations facilitate the combination of knowledge necessary to generate creative ideas (Obstfeld, 2005).

Another important outcome of social capital is power, or influence. Social capital allows individuals to gain power and influence, which can be used to achieve desired outcomes (Brass and Burkhardt, 1993). In general, the resources of social capital which are more likely to give power and influence are control and information. Controlling others and avoiding the control of others gives one the opportunity for gaining power and exercising influence over others. The information advantage can create conditions of information asymmetries that give opportunity for exercising influence.

Last, social capital allows individuals to secure a wide range of career benefits, such as finding a job (Granovetter, 1974), getting a promotion (Seibert et al., 2001), or getting a higher pay (Seidel et al., 2000). Again, it is fundamental to acknowledging that social capital could directly or indirectly affect career benefits. It can indirectly affect career benefits through the intermediation of the previous outcomes – performance and power. More specifically, individuals may be promoted, get a new job, or get a higher pay because social capital enables them to perform better. Individuals can also achieve career benefits when they exploit the power granted by social capital to better negotiate career conditions. Yet, social capital can also directly affect career outcomes, without the intermediation of performance and power. The informational advantage of social capital can expose individuals to more opportunities for finding a job. The instrumental support mechanism, through the system of referrals, can help an individual find a job, get a promotion or get higher pay. Tie characteristics, local characteristics and global characteristics have been all studied in relation to career outcomes (Seibert et al., 2001).

The Causes of Social Capital

Having established that social capital is beneficial, it becomes relevant to explain the factors that allow individuals to develop it. Research on the causes of social capital is characterized by a tension. In fact, social network theorists initially attracted the

attention of scholars because social capital was claimed to be independent of individual characteristics. While traditional perspectives were explaining individual outcomes through individual attributes, research in social capital began proposing that individual outcomes were not only dependent on the characteristics of individuals but were also a function of the characteristics of the social environment in which the individual is embedded. Therefore, for instance, to understand why someone performs better than others, we do not simply have to examine the characteristics of the individual, but also look at his or her social capital. However, if social capital is developed as a result of individual characteristics, the significance of its role would be diminished. If social capital affects individual outcomes but is dependent on individual attributes, then social capital would just be an intermediate mechanism that helps explain why individual attributes transfer an effect to individual outcomes.

There have been studies suggesting that social capital can depend on the personality characteristics of individuals. Mehra et al. (2001) highlighted that self-monitoring may be the core personality variable which explains how individuals develop social capital. Individuals differ in their capacity to read social situations and to interact with others. Individual dispositions explain why some employees are capable of developing social capital while others are not. The relationship between individual attributes and social capital still needs significant investigation. Although it is necessary to acknowledge that individual dispositions may affect the formation of social capital, it is also important to recognize that individual dispositions may interact with social capital, which can enable or constrain the expression of individual characteristics. As Borgatti et al. (2014) state, it is incorrect to assume that the behavior of individuals depends exclusively on the structure of relations and it is inappropriate to claim that social capital theory denies the role of agency in individuals. Yet, it is probably also incorrect to assume that the behaviors of individuals depend exclusively on their individual characteristics and that the social environment is a mere result of individual dispositions. Individual agency and social structures are two factors which are likely to interplay dynamically in the determination of individual outcomes.

In order to better understand the factors that influence the formation of social capital, it is important to isolate the processes through which social capital is formed. Kilduff and Tsai (2003) posit that social relationships could be formed as a result of two core processes: goal-directed and serendipitous processes. In goal-directed processes, an individual has a specific goal, perceives the need to acquire information and forms relationships in order to help achieve this goal. We can assume that for this type of formation process, the work environment may play a fundamental role in shaping social relations. Brass (1981) has found that social relations are significantly influenced by the work interdependences in the organization, which regulate the need to relate to others and acquire information. In serendipitous processes, an individual spontaneously develops social relations with others without a preexisting instrumental need that motivates the individual to address others. We may argue that personality attributes or similarity among individuals play a role here in the development of social capital.

Social Capital among Organizations

The arguments developed focus on the individual as unit of analysis. Research in social networks in sociology has been mostly concerned with describing the relationships among individuals and the core contributions to the theory of social capital focused on the individual level of analysis. However, social capital cannot only describe how relationships affect individual outcomes but also how relationships affect organizational outcomes. Instead of looking at relationships inside the organization, scholars have elaborated on the concept of social capital and explored how relationships among organizations can affect organizational outcomes.

There are different ways to elaborate on the concept of social capital and explore the relationships among organizations. One way would be to examine the interpersonal relationships among individuals in different organizations. Another way would be to explore the affiliation of individuals with multiple organizations: interlocking directorates could be an example. A third way would be to examine inter-organizational relationships as alliances. The application of the concept of social capital at the organizational level of analysis follows a logic similar to that at the individual level of analysis. There are some significant similarities in observing the effects of social capital at the individual and at the organizational levels of analysis (Brass et al., 2004). A core idea to understand the application of social capital theory to the organizational level of analysis is that of embeddedness (Uzzi, 1997), according to which social relations tend to overlap with economic relations and therefore the study of social capital can effectively explain inter-organizational relations. Even inter-organizational relations are supposed to create value because they provide access to a specific set of resources. The forms of social capital also focus on the characteristics of inter-organizational ties and the organization's position in the local or the global structure. Tie strength, brokerage, closure and centrality all have been used at the individual level as well as at the organizational level. The resources provided by social capital are similar as inter-organizational relationships also give access to information, trust, control or support. There are different outcomes of social capital studied by scholars at the organizational level but the most studied is organizational performance (Baum et al., 2014) and innovation (Ahuja, 2000).

Conclusion

Research in social capital has been and remains one of the most prolific streams of investigation for organizational theorists. The number of publications and the variety of outcomes of social capital provide solid support to the original insight that interpersonal relations create value for individuals as well as for organizations. There are some new directions which researchers are pursuing to expand our understanding of social capital. The mixed evidence in support of different forms of social capital seems to suggest that there is no universal form of social capital which gives benefits to all individuals in any circumstance. For this reason, recent empirical investigations have started to examine the contingency conditions under which specific

forms of social capital are likely to be more or less beneficial (Reinholt et al., 2011). Scholars also have started exploring the downsides of social capital and acknowledging that social capital does not only provide resources, but can also be associated with constraints and limitations that negatively affect individual outcomes (Bizzi, 2013). Scholars have begun investigating new forms of social capital: new directions point at the potential for studying relational pluralism, in which individuals simultaneously share multiple types of relationships with the same individuals (Shipilov et al., 2014). Recent research has also been devoting more attention to the origin of social capital in order to better understand when and how valuable social relations can be generated (Ahuja et al., 2012). To conclude, social capital has already offered significant advancements to our understanding of organizations and promises to continue leading our empirical investigations and enriching our understanding of the social dynamics among individuals working in organizations.

Abstract

Categorization is a process by which people make sense of things by working out similarities and differences. Social categorization is especially important because it explains the way that people make sense of other people and themselves. Studying social categorization helps us to understand the way that people perceive groups and form impressions of individuals. The big ongoing question in the study of social categorization relates to whether this is a process that works primarily by reducing information overload or generating new information.

Categorization is a psychological process that people use to make sense of the world around them. The sensemaking power of categorization comes from the idea that people understand things by working out in what ways those things are similar to some things and different from others. The process is widely studied in both cognitive and social psychology but the real interest for social psychology comes from the fact that people categorize people. That is, categorization is not just the way we make sense of objects in the world around us but it is also the way we make sense of people including ourselves. In other words, our sense of self, or our identity, is derived from a process of understanding who we are similar to and who we are different from.

Categorization is complicated, however, because as well as being a psychological process that psychologists can study it can also be used to refer to an operational process that psychologists can engage in as a scientific or quasiscientific activity. That is, just as people in their everyday lives can perceive categories of people to be, say, ingroup and outgroup members, then so can psychologists be involved in classifying people on the basis of personality type, mental disorders, roles, occupations, and abilities. Psychologists no longer participate in scientifically dubious practices that involve classifying people in terms of race.

One way of expressing this complication is to suggest that there are categories of the mind and there are categories of the world (such as the biological taxonomical category of species). Both sets of categories are important, but it is even more important to try to be clear about which sort of category we are talking about at a particular time. Categories of the world may seem to be more real and verifiable (though, of course, these can be updated as scientific understandings change as they have with the conception of race and as they do from time to time with biological species), but categories of the mind are also real because they have real consequences for the way that people understand the world. Indeed the scientific enterprise of classifying things in the world is made possible by the psychological process of categorization. By acknowledging this and by recognizing that even what seems like the strongest scientific categories are often revised as new evidence becomes available, we are reminded that it is not an easy task to judge the validity and utility of our own or other people's categories. A complex world affords many ways of understanding the same thing, and it is this capacity for mental flexibility rather than rigidity that is the hallmark of categorization as a psychological process.

Part of this flexibility comes from the power of categorization to deal with abstract ideas. A scuffle in the street between two people may be understood as interpersonal violence but if one person is a police officer and the other is a protester then it may be interpreted as routine law enforcement or as a political conflict between the government and its opponents, as state repression of free speech, or as police protecting public order and safety, and so on. All of these ways of making sense of the action rest upon discerning and applying categories and linking the categories to the interpretation of the world.

Social categorization has an additional level of complexity in social psychology because when we categorize people we also categorize entities that can categorize themselves. Consider again the scuffle in the street. A fight between two police officers or two protesters may have a completely different meaning to a fight between police and protesters. In order to understand a conflict between two people who belong to the same category, we need to understand how those people come to see themselves on different sides. In order to understand why those two people are fighting each other (rather than, say, both fighting someone else), we need to assume that those people see each other as different in some relevant way. Our system of categories helps us to understand these issues, and where they do not work well, we need to update them on the basis of new information. Violence between two police officers at a street protest might be explained in terms of a personal dislike or disagreement between the officers, but personal dislike is unlikely to be a good explanation of intergroup conflict. Generally speaking, interpersonal factors tend to provide poor explanations for intergroup processes, and to use intergroup explanations we need to categorize people into groups.

The examples we have used point to the importance of self-categorization of both perceivers and the people they perceive. The explanatory power of self-categorization rests on the power to capture possibilities. By this we mean that self-categories can and do reflect the groups we belong to now but they also help frame expectations about future

relationships. We would expect that two police officers who have a fierce disagreement at a street march could be reconciled if they were to be effectively reminded of their common duties, role, and mission as police officers. A political campaigner can promote a cause by breaking the unity of the other side and recruiting former opponents to join their side. This is only possible if the campaigner is able to imagine alternatives where people who were opponents can be seen to be on the same side. In other words, social categories are informative about selfhood (who we are) but also about possible selves (who we could be).

In this introduction we have sought to point to some of the rich nuances of complexities of social categorization. With this background in place we now turn to some of the core areas of research concern in the area. We frame this discussion in relation to two broad families of research on social categorization: the impression formation family (forming impressions of individuals taking account of their group memberships) and the group representation family (forming impressions of groups).

Before we do this, it is helpful to provide some background on some topics that have informed discussion of categorization in cognitive psychology. These topics are category representation and structure, and category learning and use.

Storing and Using Categories

Three ideas have dominated considerations of category representation and structure. These are the classical view, the probabilistic or prototype view, and the exemplar view. The classical view is that categories have all-or-none defining features that allow one category to be utterly discrete from other categories. While such categories would be logically useful it is difficult to find evidence of rules that define such categories. Wittgenstein's famous example was the concept of game where he set the challenge of defining a set of rules that include things as different as the Olympic Games and noncompetitive children's amusements all as games. The real structure of categories appeared to be that they were fuzzy in that instances were not simply members or nonmembers of a set but that some members were good instances and some were less good, and that instanced might belong to one or more set.

Two successor views to the classical view have dominated since the 1970s. The prototype view championed in the work of Rosch and colleagues holds that categories are based around an abstract summary or ideal called a prototype, and that the variation in typicality in instances is explained in terms of the discrepancies between this abstract summary and those instances: some instances are not seen to be typical members because they are very different to the prototype.

The second major alternative view was the exemplar approach. This approach suggested that a category was not stored in terms of a single abstract summary but as a set of instances (exemplars) that were encoded as traces in memory. Exemplars that were most similar to other exemplars on average would be seen to be more typical. Exemplar-based models were broadly introduced into social psychology by Smith and colleagues (e.g., Smith and Zarate, 1992) but were prefigured in work on outgroup homogeneity.

Both major approaches explained variation in typicality but they also had problems. The cognitive architecture of prototype models seemed implausible in terms of the storage of the prototype in some way separate to a set of instances. The exemplar models converged with work pointing to the distributed nature of cognition but did not offer an account as to why particular sets of instances hang together.

Some solutions were offered in relation to models that pointed to variable or mixed representation. In social psychology, self-categorization theory (SCT) offered a good example of this by positing that people could be perceived to a greater degree as individuals or as group members at different times.

At the same time interest increased in intuitive theory and knowledge as factors that could bind categories together. This was present in cognitive psychology through the work of Medin, Murphy, and Barsalou and others and through a variety of approaches in social psychology (in all cases reflecting, to greater or lesser degree, a rediscovery of the work of Bruner, 1957). A classic finding of this stream of ideas was that a disc that was midway in size between a typical pizza and a typical coin was more likely to be seen to be a pizza because people had the theory that coins were restricted by laws to particular sizes but pizzas could vary with the cook's preference.

The cornerstone of the scientific understanding of category use is Bruner's (1957) perceptual readiness formulation. This formulation suggests that the use of a category – variously referred to as the activation, application or salience, of a category – is constrained by two interacting sets of factors: those that the perceiver brings to the situation, and those present in the stimulus and/or the surrounding environment. In Bruner's model, the first set of factors is captured by the concept of *accessibility*, which refers to the *readiness* of the perceiver to employ a particular category relative to other categories. The second set of factors is captured by the concept of *fit*, which refers to the match between stimulus specifications and a particular category relative to other categories. If a category is particularly accessible, it will require a smaller degree of fit to become activated than a category that is less accessible. If a category is particularly fitting, it will require lower accessibility to become activated than a category that is less fitting. Accessibility and fit therefore jointly determine the activation and use of categories.

Bruner's "accessibility by fit" account of the category use process remains widely accepted with refinements. Higgins (1996), for example, argues that the perceiver factors can be further broken down into *availability* and *accessibility*, while the situational factors can be further broken down into *applicability* and *salience*. Accessibility and applicability refer broadly to the same processes captured by Bruner's accessibility and fit concepts, respectively. Availability refers to the presence in memory of a construct, and salience refers to those properties of a stimulus that draw or hold attention relative to other features. In both cases, these added factors constrain category use through their interaction with the other perceiver and situational factors.

The SCT (Turner et al., 1987) account of category use suggests that a category will become salient as a function of an interaction between *perceiver readiness* and *comparative* and *normative fit*. Perceiver readiness refers to the accessibility of

particular categories in memory relative to others, but also captures the perceiver's long-term theories with regard to categorizing the world, as well as the perceiver's current expectations, motivations, values, goals, and needs. Comparative fit refers to the degree to which stimuli that covary with an organizing principle (such as a category label) are on average more similar to one another than those stimuli are to all the remaining stimuli in the perceiver's current psychological frame of reference. Normative fit refers to the degree to which the category specifications defined by the comparative relations are in the direction expected by the perceiver, based on his or her background theories and previous experiences. The salience model proposes that categories that the perceiver is particularly ready to deploy will require lower comparative and normative fit to become salient than categories that the perceiver is less ready to deploy. Similarly, when comparative fit within a stimulus field strongly favors a particular category, then the perceiver need not be as perceptually ready to deploy that category for it to become salient. The key point within all models that build on the perceptual readiness formulation is that the interaction of perceiver factors and situational factors will act together to determine category use.

Forming Impressions of People

Although category use is widely accepted to function in the way described by the perceptual readiness formulation, some researchers argue that certain types of categories will be automatically accessed and/or automatically applied, irrespective of readiness or fit-type factors. These researchers – who variously describe human perceivers as cognitive misers, mental sluggards, motivated tacticians, and efficiency experts – argue that the categories of race, age, and gender are particularly likely to be used, and that their use will occur involuntarily and outside the perceiver's conscious awareness. From this perspective, categories are thought to be simplifying or streamlining devices that allow a perceiver to quickly and easily relate to a novel person based on that person's group membership. Race, age, and gender are thought to be used automatically because they apply to almost any novel person a perceiver might encounter, because they are visually available immediately upon encountering a novel person, and because the stereotypes associated with them provide perceivers with rich but streamlined chunks of prior knowledge on which to base their judgments.

Research in this tradition has focused on impressions of people as unique exemplars or as group members, depending on the perceivers' goals and motivations. A particularly prominent model is the continuum model of impression formation developed by Fiske and Neuberg (1990). This model endorses the notion that categorization is an effortless process employed by perceivers to simplify perception. The model argues, however, that categorization is only one of two complementary processes in the perceiver's social cognitive toolkit, the other being the process of *individuation*. Individuation is said to be a more effortful, richer process than categorization, one that focuses the perceiver on a target person's individual-level characteristics rather than his or her group memberships. The model posits that impression formation proceeds along a continuum, anchored at one end by categorization and at the other end by individuation, and that movement along the continuum is mediated by a perceiver's motivations, and his or her resultant deployment of available cognitive resources. Perceivers who are unmotivated to form accurate impressions of a target person will use group memberships to make sense of the target, remaining at the proximal end of the continuum. When perceivers are motivated, on the other hand, they will deploy their limited cognitive resources and attempt to form a more individual-level, attributed-oriented impression of the target, thus moving further toward the distal end of the continuum.

A key consideration within the impression formation family of research has been cognitive load. Given that the deployment of cognitive resources is thought to be central to a perceiver's transitioning from categorization to individuation, the availability or otherwise of those resources prior to the deployment of them has been a central focus of research. Research has consistently shown that stretching a perceiver's cognitive resources – known as imposing a *cognitive load* – leads the perceiver to refer more heavily to stereotypes associated with the target's group memberships when describing the target than when the perceiver's resources are not stretched. A typical example of this finding can be found in the experiments of Gilbert and Hixon (1991).

Despite the wealth of research supporting the idea that categorization is driven by a need to reduce cognitive load other views have emerged. The meaning-seeker approach, which arose from the social identity tradition, assumes that perceiving a target in terms of his or her group memberships is an adaptive, useful, and valid way to structure one's understanding of the social world, and not merely a way to deal with complexity, nor simply a way to effectively balance accuracy and efficiency concerns. Categorization may be an effortful process and not simply an energy saving device.

A recent challenge to the primacy of cognitive load has recently been made. Skorich and Mavor (2013) have pointed out that the traditional understanding of social categorization as an efficient group-based process is problematic, because it hides the fact that the source of categorization's purported efficiency can be dissociated from the group-level of representation at which categorization is usually assumed to function. These researchers argue that the categorization and individuation concepts, as traditionally discussed and experimentally operationalized, can be thought of as confounding a group/person dimension and a memory-based/data-driven dimension. Given that the term 'categorization' is always used to mean both 'group' and 'memory-based' and that the term 'individuation' is always used to mean both 'person' and 'data-driven' it is impossible to determine which dimension is the source of the efficiency advantage of categorization relative to individuation. Skorich and Mavor were able to demonstrate that cognitive load privileges memory-based over data-driven processing, not group-level over person-level processing. These findings call into question both the efficiency of categorization as it is traditionally understood and also the traditional 'group as category' understanding of categorization.

Also arising from the impression formation family has been a line of research exploring whether the processing of faces might be related to the efficiency of categorization. Macrae and

his colleagues (e.g., Macrae et al., 2005; Pendry and Macrae, 1994) have shown, for example, that (1) diagnostic cues in a face are important for sex and race categorization, particularly under suboptimal (blurred or inverted) processing conditions, (2) mere exposure to a target face does not necessarily lead that target to be categorized by its sex, (3) multiple social categories are processed within a face without impacting on the categorization outcome, (4) manipulating diagnostic cues can lead participants to falsely respond that a male is female and vice-versa, and (5) perceivers are faster at responding that a face is male or female than they are at responding that a face belongs to a familiar or unfamiliar person, particularly under suboptimal (blurred or inverted) processing conditions. All of these findings have been related back to the idea that categorization is a simple and efficient process, and that its simplicity and efficiency derives from the immediate visual availability of categorization cues, in the face.

Forming Impressions of Groups

An issue of central importance to both prototype and exemplar theories of categorization is the variability within and between categories and what that variability is attributed to. Interest in the perception of social category variability developed extensively under the banner of group homogeneity, with a particular emphasis on the outgroup homogeneity effect (OHE) and associated implication for stereotyping. The source of those perceptions of variability could logically arise from three sources: the target, the perceiver, or the context, which are the focus of three different theoretical perspectives.

The concept of entitativity focuses attention on the target of perception itself; that is a target (group or person, for example) might be perceived to have more or less entitativity (Hamilton and Sherman, 1996). A different literature explores the individual differences in the expectations of the perceiver. The implicit, lay theory of person perception (in the work of Dweck, Levy, and colleagues) suggests that perceivers might be predisposed to think of persons as being either very stable or quite variable, and this perspective has been extended to group perception as well. The third possibility is that perceptions of variability arise primarily from the context in which the judgments are being made. SCT has particularly focused on this aspect as a conceptual complement to the other perspectives though SCT, in fact, broadly embraces all three possibilities. Work on the illusory correlation effect also focuses attention on the context in which the stimuli are perceived, though in quite different ways. We explore in more detail the notion of social category homogeneity in the following section, and then further perspectives based on the target, the perceiver, and the context.

Interest in homogeneity and the link to stereotyping goes back to early twentieth century work on perceptions of the relative homogeneity of stereotypical perception of actual groups, but the observation that other groups tended to be rated higher in homogeneity (and hence stereotyping) than one's own group led to a large body of work on the OHE as an explanatory process in stereotyping.

Several explanations were proposed. One well-explored possibility was that we are more familiar with ingroups than outgroups and that familiarity increases perceptions of heterogeneity (Linville et al., 1986), or that the greater amount of information available for ingroups made it more robust to forgetting effects. Relatedly, outgroups were proposed to be represented primarily in the form of prototypes, while ingroups might be represented as a mixture of prototype and exemplar representations (Park and Rothbart, 1982). These explanations seemed consistent with a tendency to find null effects for gender groups, where presumably we are more equally familiar, compared to racial and other types of groups, but ultimately some gender effects have been found, undermining the importance of familiarity explanations. An alternative, contextual explanation was made by S. Haslam et al. (1995) who argued that in many OHE studies, judgments were made either for ingroups alone (which would be an intragroup context) or of an outgroup (which would be intergroup). The intragroup context may create a focus on variability whereas intergroup may focus on homogeneity. As this line of research developed, several reviews and meta-analyses appeared, but no clear universal explanation emerged. The 'effect' is quite small, which undermines any simple explanation, but most likely several processes, in particular status, personal identity salience, and group size, can contribute to perceptions of group homogeneity.

Other developments of the homogeneity literature explored different ways of understanding the notion of variability. Early work by Linville and colleagues tended to focus on the proportion of group members holding some characteristic, but subsequent work explored the possibility that we might represent variability information in the form of distributions of exemplars or that we have a more complex understanding of the interrelations of attributes associated with different subtypes of a category.

The Entitativity Continuum

A different approach to thinking about category representation developed around the idea of the entitativity of a social target. Campbell (1958) developed the idea of entitativity, based on Gestalt theory concepts, to capture the extent to which the characteristics of a group would make it more likely that an aggregate of members would be seen to have some collective quality – to be seen as an entity. Hamilton and Sherman (1996) revived the entitativity concept as a way of exploring two key issues: the extent to which person and group targets could both be seen as entitative or not, and the implications for underlying cognitive representation and judgment. Hamilton and Sherman argued that when a target is seen as an entity, perceivers are more likely to make online judgments about that target. As each piece of information is processed, it is incorporated into an integrated representation of the target and that any affective judgment of the target will also be constructed during the impression formation. By contrast, if a target is not seen as particularly entitative when impressions are formed, then the pieces of information are more likely to be loosely organized in memory and not connected to a central concept of the target. When perceivers are subsequently in a position requiring a judgment of the given target, those who processed the impressions online would have a better overall memory of

the specifics and a tendency to recall earlier material (which would be closer to the core of the representations in memory). Those who did not process the impressions online would have to actively assemble the impressions at the time of (memory-based, or retrospective) judgment, leading to lower overall recall and more reliance on recent impressions.

The studies by McConnell and colleagues supported several key assertions from Hamilton and Sherman (1996). Person and group targets could both be seen as having some degree of perceived entitativity and to vary along a common continuum representing a common perceptual process. This has implications for the recall of information about both types of targets. It was also possible to manipulate the expectation of entitativity, such that both person and group targets could be explicitly made to be seen as more or less entitative, with associated affects on memory processes and judgments, reflecting an important influence of the context. Finally, McConnell and colleagues found evidence to support the idea that a person target tended to be seen as more entitative by default (in the absence of their explicit manipulations) relative to a group target. Hamilton and Sherman (1996) interpret this latter finding as indicating that persons will be assumed to be entitative but that groups may vary more widely and this has led to a line of research to catalog the perceptions of entitativity of different kinds of groups (e.g., work groups, families, broad sociological categories) and in the process has provided a mechanism for exploring the underlying dimensions on which perceivers may attribute entitativity to a target. Sherman and colleagues have proposed that the online/memory-based processing distinction and the tendency for persons to be seen as higher in entitativity could be a basis for dual-process distinction between person and group impression formation.

There are also some important lines of qualification of these ideas. Crisp and Hewstone (2007) and others have explored the important moderating effects of multiple social categories. The key insight here is that perceiving persons in terms of more than one category membership can have moderating effects on categorization (that may, for example, encourage more nuanced and accommodating views of minorities). In a different vein, N. Haslam and colleagues have emphasized the importance of particular category content. Certain categories are perceived to have forms or qualities that imbue them and make them seem especially different from others. These essentialized categories include biological categories. Good examples of these essentialized categories appear in work on dehumanization where it has been argued that certain categories of people can come to be seen as lacking human qualities and thus to be more like animals or machines (Haslam, 2006).

Controversies and Enduring Issues

The study of categorization continues to offer a number of choice points or unresolved issues. One that we have referred to above is the issue of whether categorization is driven by information reduction or meaning creation and whether there are new intriguing ways to recast that question. A second issue that we have not dealt with here (but see McGarty, 1999) is the question of what form do organized systems of category structures take? The idea that categories are organized into hierarchies (so that lower level categories are completely contained within higher order categories) is appealing (and underpins the work of Dovidio, Gaertner, and colleagues on recategorization), but there are good reasons to doubt its applicability to many category systems of the world and of the mind.

The longevity of category structures and the extent to which they are fixed or stored in the mind is also a good point to debate. It is tempting to think of categories as structures that are stored and retrieved (like books in a library) but this is an outmoded view of cognition. It may be better to think of categories as structures that are spontaneously generated or constructed in response to context.

Finally, we have focused a great deal here on classic social categories that are based on sets of people who share a demographic feature. There are also social categories based on people who share opinion, emotion, or role as we have explored in some of our work. However, is it possible to go deeper than that to address 'social' categories that might not relate to different people sharing the same attribute but to the same person having different attributes that apply to that person at some times and in some contexts? Are the same principles of categorization applicable to these intrapersonal categories, or do instead the principles derived from studying the new forms of social categories lead to a reconsideration of the classic forms? Whatever the answers it is certainly true that the study of social categorization will remain one of the most fascinating fields in social psychology and beyond.

Abstract

This article defines models of social change in terms of how established social forms – rites, tools, languages, structures, hierarchies, and rules, whether they are simple or complex – are maintained or changed. It commences by citing the distinction of social facts from individual actions, identifies three requirements of theories of social change, shows how the 'Population, Organization, Environment, and Technology' (POET) model can be used to understand the loci of change identified in different models of social change, focuses on actors and structures and actor assumptions and structure assumptions as key elements of models of social change, and notes the distinctions of intentions of actors from the effects of their actions and expectations from desired consequences. The article concludes by identifying examples of formal systems – mathematics, statistics, and computational algorithms – that have been used to develop and assess models of social change.

Introduction

There is an amazing multiplicity of social forms: rites, tools, languages, structures, hierarchies, and rules. How has this variety come about and why is it forever changing? Yet, most of the time, humans behave like those around them. How has this conformity developed? And why is it maintained?

Models of social change address these questions. What generates change, and is it differentiating or uniforming? What maintains established structures, whether they are simple or complex?

Classicists, such as Durkheim, Marx, and Weber, provided models of the transformation as well as the preservation of social forms and analyzed diversification as well as homogenization. This they did, not so much by general theoretical statements, as by laying bare the social logic driving specific historical passages. They can be used to highlight models of social change and provide paragons that present-day studies can be appraised against.

Individual Actions and Social Facts

Durkheim, in *Suicide* ([1897] 1951) sought to explain both constancy and variety. He asked: "Why are suicide rates so stable – indeed, more stable than ordinary death rates – and yet variable systematically between groups?" Why do they take on a new stubborn stability after marked shifts? Durkheim held stable but differing suicide rates to be social facts. They exist relatively independent of the individuals who compose the group on which they are measured. Social facts – e.g., the language we speak, the rites we share, or the streets we walk – endure, Durkheim argued, *sui generis*.

'Social facts' have an existence of their own, like a swarm of moths which can change its shape or shift its position – yet, of course, there are no social phenomena without individuals being part of them; no swarm without the ephemeral movements of individual moths. Put paradoxically, social facts – both changing and constant – are relatively independent of those on whom they depend. Individuals are held in place by their fellows and take their cues from each other. This is important in the study of social change; it is always mediated through individuals who are shaped by their physical and social environment before they can act on it, and who change it by reacting to circumstances that they have brought forth or that are transmitted from the past.

'Social change' is at the core of sociological analysis. Yet, few studies cover the whole cycle of analyzing "how [individuals] react to conditions of their own making and in so doing change these conditions" (Hernes, 1976, p. 513). Rather, they present snapshots of a condition, such as a poll of opinions or their causal determinants. The reasons are many; collecting data as a process unfolds is costly and time-consuming. Data from other sources do not easily lend themselves to analysis over time. Survey techniques often result in a kind of aggregate social psychology rather than studies of structural change; and when a survey restricts itself to "enumerating individual characteristics, [it] treats the individual as if [she/he] were detached from [her/his] environment and hence as an abstraction" (Boudon, 1971, p. 48). Indeed, the methodological successes of survey analysis can lead to conceptual failures. Consequently, most social scientists do not go into deep analysis of social change even if it is at the core of social analysis.

Requirements of Theories of Social Change

From the above observations, three logical requirements of models of social change can be identified (Hernes, 1976). First, it should be possible to use the same basic approach in studying both constancy and change. This implies that a stable structure should be seen as a process in (temporary) equilibrium and that the theory must include an explanation of why the forces or parameters governing a process themselves are regenerated. Structural change must be described in terms of the processes that generate the change. Structural stability must be explained in terms of the processes that not only maintain

the stability, but also maintain the processes that maintain the stability.

Some accounts are static, e.g., 'percentage unemployed.' Yet, from a model point of view, it not only makes better sense, but also makes for more interesting analysis, to conceptualize even 'static' phenomena in terms of processes. For example, if the number unemployed remains stable, this does not imply that the same individuals remain out of work – only that the flows of individuals in and out of employment cancel out. Hence stability can be viewed as a process in equilibrium (Coleman, 1964).

Secondly, models of social change should incorporate intrinsic sources of change. Changes in social systems may be induced from the outside, but all changes cannot be thus induced (Elster, 1971). Even when the impetus for change is imported, the mechanisms transmitting external impacts should be identified. Indeed, when an item is taken from the outside, it should be possible to employ the same kinds of explanations for its adoption as if it had been invented at home. Moreover, the sources of change should also be intrinsic to the theory, in the sense that effects of previous actions provide or change premises for further choices of action.

Lauriston Sharp (1952) gives an example in 'Steel axes for Stone Age Australians.' He describes how the aboriginal Yir Yoront group as late as the 1930s, lived an essentially isolated and independent economic existence based on Stone Age techniques. However, "their polished stone axes were disappearing fast and being replaced by steel axes which came to them in considerable numbers, directly or indirectly, from various European sources to the south" (Sharp, 1952, p. 17). Sharp discusses the changes in the lives of the group that resulted from the replacement of the stone axes around which their culture was built. For example, stone axes were an item of trade and hence important in intertribal relations, as well as in belief systems, celebrations, and totemic ceremonies. Men crafted the stone axes, which were a symbol of their masculinity; yet they were lent to women who used them in their heavy chores. He notes that "The shift from stone to steel provided no major technological difficulties" (Sharp, 1952, p. 20). Sharp then analyzes how this change of tools changed trade relations, gender interactions, and authority structures:

> The most disturbing effects of the steel axe, operating in conjunction with other elements also being introduced from the white man's several sub-cultures, developed in the realms of traditional ideas, sentiments, and values. These were undermined at a rapidly mounting rate, with no new conceptions being defined to replace them. The result was the erection of a mental and moral void which foreshadowed the collapse and destruction of all Yir Yoront cultures, if not, indeed, the extinction of the biological group itself (Sharp, 1952, p. 21).

Here the new technology came from the outside – the impetus for change was exogenous. But its adoption is explained in terms of simple principles at the level of the actors: steel axes were nearly free, good tools, simple to use, and requiring less effort – the same advantages that would accrue if they had been invented locally. But the effects of this *deus ex machina* changed the premises for further choices of action, in this case with devastating aggregate effects; it reduced women's dependence on men, it undermined belief systems, it wrecked havoc with traditional trade relations and their social embellishments.

Finally, as just seen, social change is mediated through individual actors. Hence the third requirement of theories of social change: they must show how macrovariables or structural characteristics affect individual motives, capacities, and choices; and how the choices of actors, in turn, change the macrovariables. For the Yir Yoront, adopting a new tool changed their social structure in ways that were no part of their intention.

Loci of Social Change and the POET Model

Next the loci of change need to be identified. At a most general level of analysis, a classical theoretical model originally developed in human ecology is useful in this task. This model identifies four elements of a human system at the societal level, that is, Population structure, Organization, Environment, and Technology, and hence termed the 'POET' model. Within the POET model, "An ecological account of social change is attempted by referring to such instigating factors as environmental change [E] (whether caused by man or other agencies), changes in size and composition of population [P], introduction of new techniques [T], and shifts in the spatial disposition or organization of competing populations [O]" (Duncan, 1959, p. 683).

At the broad population level of analysis, 'Population structure' [P] refers to the age, race, and sex composition of a society's population and to its spatial location and distribution. Population structure has very significant consequences for demographic processes of reproduction, survival, and growth, i.e., fertility, mortality, and migration and for social processes and structures such as social mobility and inequality.

'Organization' [O] is a multifaceted term that refers to the ways in which a society is organized to maintain itself, i.e., its 'sustenance organization.' A major dimension of sustenance organization is 'sustenance differentiation,' that is, the "arrangement of differentiated parts suited to the performance of a given function or set of functions" (Hawley, 1950, p. 178). Sustenance differentiation is a major component of the division of labor. A second dimension is 'functional interdependence,' which can form the other side of the division of labor by combining with sustenance differentiation (Gibbs and Poston, 1975). A third dimension is the 'volume of sustenance produced by the population,' i.e., "the degree of productivity of the particular configuration of sustenance activities" (Poston and Frisbie, 2005, p. 609), which may include agricultural productivity, retail services productivity, wholesale services productivity, personal services productivity, etc. A fourth dimension is the 'extent of efficiency of the sustenance organization,' which can be measured by the ratio of the amount of sustenance produced to the amount of inputs needed in the production process. A bigger ratio indicates higher efficiency. A final dimension is the "degree to which population members are engaged in sustenance-related pursuits" (Poston and Frisbie, 2005, p. 610). Related measures of this dimension can be the labor participation rate in the

population and the extent to which social status is ascribed or achieved.

The Environment [E] concept in the POET model does not comprise everything external to the phenomenon under investigation, "but only those externalities that, by virtue of the limits they set on the acquisition of sustenance, affect the life chances of an organized population with a given technological repertoire" (Poston and Frisbie, 2005, p. 615). Thus, the environment concept in the POET model is a set of conditions serving as limiting (or enabling) resource for the adaption and growth of societal populations, whose breadth depends on "the technological devices and modes of organization that prevail in a given population" (Schnore, 1958, p. 628; Poston and Frisbie, 2005, p. 615). Based on this definition, social and economic activities (e.g., unemployment rates, industry structure, levels of education and income etc.) are not part of the environment. Rather, the environment concept in the POET model has two broad and distinct dimensions: the physical and the social. The physical environment refers to climate, natural resources, topography, etc. The social environment includes factors, such as the size of a population, proximity to the nearest metropolitan areas, and government influences.

Among the four basic elements of the POET model, 'technology' [T] plays a critical role in the adaptation and growth of human populations to their environments because it sets the boundaries for possible social and economic development (Poston and Frisbie, 2005, p. 611). Technology has three dimensions: material features (tools, capital equipment, machines); information (knowledge, techniques, scientific discovery); and energy (Poston and Frisbie, 2005, p. 612). Gross Domestic Product (GDP) per capita often is taken as an overall index of the hardware, capital-equipment, and information dimension of technology of a society.

Application: Explaining Increasing Economic Inequality

The POET conceptual model originally was developed, and traditionally applied, at a broad level of social organization, the societal–human population level, with its focus on "… the organizational aspects of human populations that arise from their sustenance-producing activities" (Poston and Frisbie, 2005, p. 603). Its comprehensive conceptual framework can be used to organize and synthesize studies of large-scale social change. For instance, a societal trend in the United States and many developed countries since the late 1970s that has received considerable research attention recently, is growing economic inequality, a specific organizational aspect of human populations that arises from sustenance activities. Social scientists have observed this trend in various statistical measures of inequality for decades. Sufficient time has elapsed for the impacts of social changes to become evident, for time series of annual measurements to be constructed, and for conceptual models to be developed, estimated, and evaluated empirically, to identify the important social forces driving the inequality trend. These contributions incorporate elements of the POET model in various ways.

One of these studies is Kristal (2013), which analyzed the decline in labor's share of national income and the rise in the capitalist's share of profits. From the late 1970s through the 2000s, labor's share of national income declined by 6% across the US private (nongovernment) sector of the economy. This overall decline in labor's share resulted from a large decline (5–14%) in construction, manufacturing, and transportation combined with a small increase (2–5%) within the finance and service industries. Kristal's (2013) conceptual model identifies erosion in workers' positional power as the main factor leading to the decline in labor's share of profits and posits that this erosion was partly an outcome of technological change in the form of computerization that favored capitalists and high-skilled workers over most rank-and-file workers. Controlling several parameters of workers' positional power (unionization, capital concentration, import penetration, and unemployment), she studied the direct and indirect effects of computer technology on changes in labor's share in US nonagricultural private and manufacturing industries, finding considerable support for the model.

In brief, the key explanatory variable in Kristal (2013) is a form of exogenous technological change (a specific form of the T component of the POET model) that led to large changes in an income inequality measure of the organizational structure of sustenance activities (a specific measure of an element of the O component of the POET model) in the United States. By comparison, Lin and Tomakovic-Devey (2013) focus on the impacts of changes in industry-level financialization (another element of the O component) – the increasing dominance of the finance sector of the economy as measured by the ratio of financial receipts (interest, dividends, and capital gains) to business receipts from the selling of goods and services – on increasing income inequality in the United States for the years 1970–2008. Three measures of income inequality (labor's share of national income, the income share of top earners, and earnings dispersion among workers, all of which are elements of the O component of the POET model) were studied. Net of controls for deunionization of the labor force, globalization of the world's economy, and capital investment (three elements of the O component of POET) and technological change (a T component), Lin and Tomakovic-Devey (2013) conclude that financialization could account for substantial proportions of the changes across the decades in the three measures of inequality.

A third study, Dwyer (2013), highlights yet another factor to the explanation of economic restructuring and job polarization (an element of the O component of POET) in the US labor market, namely, the growth of care work (another element of the O component of POET). Care work jobs are defined as service jobs that contribute to the health, well-being, or development of other people, services that once were mainly provided within families and kin networks rather than in market exchange. Dwyer (2013) shows that much of the increase in job polarization from 1983 to 2007, as measured by the growth of jobs with pay levels in the lowest and highest job wage quintiles as opposed to middle-wage jobs, and especially the growth of jobs for women, is related to an increase in care work jobs, which also tend to be concentrated at lower and higher ends of scales of job skills and labor market power. The growth in care work jobs, in turn, has been driven by changes in the societal organization of sustenance activities such as increases in female labor force participation and

changes in family structures toward smaller localized kin networks (elements of the O component of POET) and a population age structure that is increasing at the older ages due to increased longevity (an element of the P component POET).

In brief, each of these three studies adds knowledge of the forces that have driven recent increased levels of economic inequality in the United States (with similar patterns having occurred in other developed countries). Yet, the loci of change in all three studies are well encapsulated within the POET conceptual framework: the locus of change in Kristal (2013) is an exogenous change in technology (T); Lin and Tomakovic-Devey (2013) highlight the importance of a change in sustenance organization (O); and Dwyer (2013) focuses on changes in the job structure that have been driven by changes in sustenance organization (O) and population structure (P).

Actors and Structures

While the preceding application focused on societal-level processes, the four basic elements of the POET model also are present at the intermediate and smaller levels of social organization down to the smallest level of social organization, the primary group. Even at this smallest level of social organization, the actors (population) and their social structures (networks of social ties and interactions) and the social structures (organizations) within which they operate (families, neighborhoods, voluntary associations, work places) can change. In addition, the environment of a primary group conceived of as enabling resources for interactions and continued existence/survival of the group, may be of key importance. Similarly, the technology available to the group may affect its forms of interaction, e.g., whether face-to-face or via electronic media.

At smaller (than population) levels of social organization, and for relatively short-time spans of analysis, models of social change may be constructed on the presumption that the environment and technology components of the POET model are fixed and unchanging, although possibly variable across a set of units to be analyzed. The minimal components of models of social change must, therefore, include two sets of abstract elements – actors and structures – to mirror what drives the changes in them (Hernes, 1989, 1999).

Hence, the first element to specify in a model of social change is the 'types of actors' assumed to operate. In the language of the theater, specifying the actors corresponds to the casting of a play. For example, in microeconomic theory two types of actors are distinguished: consumers maximizing utility by spending their resources to obtain goods, and producers maximizing profit by the quantities they market.

The second element to specify is the structure in which the actors are embedded – the staging of a play. For example, in microeconomic theory three main market structures are distinguished: perfect competition where the actors are so many and small that none of them can affect the price; oligopoly, where the producers are so few that they react to each others' decisions; and monopoly, where a single producer can set the price.

One reason for combining actors and the structure within which they operate, is to construct a model so that one can logically work out the systemic effects of actors' choices within the structure – the plotting of the play. The point is to answer questions about what happens to the actors or to the structure as a consequence of the actors reacting to the initial conditions – i.e., the logical sequence of consequences that flow from the assumptions made. In other words, we construct models of actors within a structure in order to understand what the actors are doing and why, to explain what results from their actions and why, and whether the results are intended or not – a logical narrative. A logical narrative may have logical flaws and hence be theoretically unsound. And one such logical narrative may exclude others: it simultaneously empowers our reasoning and limits our comprehension – both our understanding of the actors and the explanation of the results of their interaction.

A second purpose is to compare the logical outcomes of the model to a real-life sequence of events. A compelling argument may be empirically false – the logical narrative may not match the historical record. Hence, if the model is to provide a valid understanding or a tenable explanation, there must be a rough goodness of fit between what the model logically leads us to expect about what will transpire and what actually takes place in the real world. The model cannot just be plausible in theory – it must at the end of the day be admissible by the facts; the observed must agree with the inferred. If the model is ruled out by the facts, it must be discarded and another constructed from different assumptions that provide a more realistic understanding and credible explanation.

For example, the simple model of perfect competition implies that profits will tend toward zero. If we observe that profits in fact are high, we may modify the model to better account for this fact by changing the assumptions, e.g., by allowing producers to change consumers' attitudes (advertising) or by allowing for monopolization – i.e., discarding the model of perfect competition.

Specifying Actor Assumptions and Structure Assumptions

To give a logical portrait of the types of actors involved in a social process, the following kinds of questions must be answered:

1. What do they *want* – what are their preferences or purposes?
2. What do they *know* – what are their beliefs, their potential for changing them or for learning?
3. What can they *do* – what are their capacities or skills?

Sometimes answers are only rudimentarily specified, e.g., in models of contagion where contracting a disease clearly is not something sought but something caught.

Actor assumptions allow us to understand what actors can do, what they actually do and why, or how others react to them and why.

A similar set of questions must be answered to specify assumptions about the structure:

1. What alternatives or constraints do the actors face? These may span from opportunity for migration to household budgets. They include collective properties such as laws and norms and physical barriers such as roads or rivers.

2. What social positions can the actors hold – e.g., organizational roles. What are the correlates of positions – e.g., their status or the hierarchy of wages linked to a given division of labor? Rewards, rights, and burdens are structural correlates of positions – they also define, fix, or freeze the alternatives actors face.
3. What are the distributional characteristics of actors, as distinct from their individual manifestations? For example, the number of other actors may affect options as in perfect competition, or the age distribution may affect outlooks for marriage. The sex ratio and the population pyramid are 'population structural' characteristics.

Specifications of the actors' attributes are needed to understand what they do and why. Specifications of the structure – options and payoffs – within which the actors make choices and act, are needed to explain what happens and why. These two sets of assumptions are needed to construct the logical narrative of systemic effects.

Intentions versus Effects and Expected versus Desired Consequences

The distinction between actors and structure is useful when what happens deviates from what was anticipated. In 1936 Robert K. Merton wrote a famous article on *The unanticipated consequences of purposive social action* (Merton [1936] 1976). A key point is that actors' choices and purposive actions (intentions) may interact to produce unanticipated consequences (effects) that were not part of the intentions. This notion is very useful for describing models or mechanisms of social change. The net outcome of rational choices may be counterintuitive. The way to hell may be paved with good intentions and simultaneous choices based on the best of motives may be made counterproductive by some hidden hex. Sometimes actors are caught by what they have wrought; sometimes they do not master the world they have made. Such unintended effects, counterproductive actions, and counterintuitive results, which flow from the actors' choices rather than their intentions, often produce engaging logical narratives.

The simplest models of change are, of course, when purposive actors produce intended results. What appears is what was planned, what materializes is what was sought. However, sometimes what turns up is not what the actors had in mind. Sometimes their best intentions interact to produce self-defeating results, as when a stampede to get out blocks the exit. Sometimes selfish motives produce positive overall effects over and beyond their expectations, with improved welfare coming as a by-product, as if an invisible hand guides self-interest to produce efficient use of resources. As the argument runs in Adam Smith's classic text:

> He [every individual] generally, indeed, neither intends to promote the public interest, nor knows how much he is promoting it. By preferring the support of domestic to that of foreign industry, he intends only his own security; and by directing that industry in such a manner as its produce may be of the greatest value, he intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention. Nor is it always the worse for the society that it was no part of it. By pursuing his own interest he frequently promotes that of the society more effectually than when he really intends to promote it. I have never known much good done by those who affected to trade for the public good. It is an affectation, indeed, not very common among merchants, and very few words need be employed in dissuading them from it (Smith [1776] 1937, Book 4, Chapter 2).

A key point for the analysis of social change is that what results, whether it appears as the compelling influence from a hidden hex or an invisible hand, flows from the actors' choices, not from their motives. That is why understanding the actors is not sufficient – explanation of the interworkings of their actions beyond their intentions, expectations, or belief is necessary. Simultaneous choices based on the best of motives may be counterproductive. The net outcome of rational choices may be counterintuitive. Silly choices may prove lucky strikes; bad motives may result in good fortunes. The way to hell may be paved with good intentions just as private vices may give public benefits (Mandeville [1714] 1989).

In fact, we can classify types of explanations from the answers to two questions: "Were the consequences expected or not?" and "Were they desired or not?" If the results coincide with what was desired, the actors have produced the intended results.

If the results were not expected, but are desirable when they appear, we have what could be called 'invisible hand' explanations, since they are of the kind illustrated by the quote from Adam Smith above.

The cases where the consequences are expected but not liked by the actors when they turn up, can be termed 'suboptimality' (cf. Elster, 1978): the actors know that when they act in their own interest, they nevertheless collectively end up in an undesired state – the joint outcome of their choices makes them worse off. 'The Tragedy of the Commons' illustrates the logic. A 'commons' is any resource that can be used as though it belongs to all. However, when rational agents use it, such a shared resource is doomed, though this is no part of the users' intent. Everyone gains from using it, none gains anything from not taking out what they can when others do. When utilized near carrying capacity, additional use will degrade its value to all. "Ruin is the destination toward which all men rush, each pursuing his own best interest in a society that believes in the freedom of the commons" (Hardin, 1968). The inexorable working out of the resource's ruin is Hardin's 'tragedy of the commons.' Social change is the consequence of the sum of self-interested actions. And all could be better off by restraints on their own actions. If such collective restraints are imposed by the actors themselves, this represents a change of political structure. This latter logic and model of structural change was first suggested by Thomas Hobbes ([1651] 1982) who called the commons 'the state of nature' and 'war of all against all,' whereas the joint establishment of an authority to keep all from self-defeating actions he called Leviathan (cf. Hernes, 1999).

The fourth case is where the actors misjudge what others will do. Intentions that could be realized under constant conditions are rendered impossible when everyone seeks to realize them and change the conditions. 'Hog cycles' is an

		Are the consequences desired?	
		Yes	No
Are the consequences expected?	Yes	Intention = consequence	Suboptimality
	No	Invisible hand	Counterfinality

Figure 1 Actions and consequences.

economic example: producers act on the same assumptions and overinvest or underinvest in concert – the results of their decisions appear too late to become premises for their decisions. Erosion is another example – the irreversible destruction of alternatives. With a term Elster (1978) borrows from Sartre, this could be called 'counterfinality.'

The four kinds of models are summarized in **Figure 1**. Sometimes the actors get caught by what they have wrought; sometimes they do not master the world they have made. But independent actions can also turn out to be blessings in disguise.

Formal Models of Social Change

Models of social change may be expressed in a variety of formal systems – mathematics, statistics, and computational algorithms. Space limitations do not permit a systematic exposition, but a few examples can be cited.

Social change models expressed in natural language generally are articulations of qualitative explanations and often are found in studies of broad historical social change, as in the classical studies of Durkheim, Marx, and Weber. Verbal models of social changes also often are starting points for the development of more formal models. Examples are Herbert Simon's (1952) model of verbal theory of the intensity of interaction among members of a social group, the level of friendliness among the members, and the amount of activity carried on by members within the group; and Land's (1970) model of Durkheim's ([1893] 1933) verbal theory of the causes of the division of labor in society. These formal models were expressed in the form of deterministic differential equations that model change in continuous time, in order to provide formal representations of the dynamics of change in the theories of Homans and Durkheim, which potentially could be subjected to quantitative empirical estimation and testing.

Since the publication of James Coleman's (1964) 'Introduction to Mathematical Sociology,' stochastic differential equation models that model dynamics in continuous time in probabilistic form, and, more generally, stochastic models of change in both continuous and discrete time (Bartholomew, 1982) have become widespread. These models often can be conveniently estimated empirically by application of statistical estimation methods such as maximum likelihood (ML) (Wasserman, 2004). Statistical models extending from simple cross-tabulations to regression models to structural equation models (SEM) (Bollen, 1989; Kaplan, 2009) are also widely used formal representations for the study of social change. Indeed, SEM modeling recently has been applied to the ML estimation of stochastic differential equations (Singer, 2012). In addition, a variety of statistical models for time series analysis (Jaffe, 2000) and pooled time series–cross section/panel regression models (Woolridge, 2002), including autoregressive, distributed lag/error correction models (Beck and Katz, 2011) have been extensively applied.

All of these stochastic/statistical models tend to model the temporal dimension as historical or 'period-time.' In addition to period-time, demographic models of population processes have focused on age-time in order to take into account the age dependence of many demographic and social processes, as in classical life table models, or on both age-time and period-time, as in stable population theory (Keyfitz, 1977). A third temporal dimension also often is distinguished in studies of demographic and social change, namely cohort-time, which leads to age–period–cohort (APC) statistical models of change (Ryder, 1965; Mason et al., 1973; Yang and Land, 2013).

The foregoing mathematical and statistical models often are applied to the study of large-scale social change. Models of social change at smaller scales that focus on the motives, expectations, and consequences of actions of individual actors often use network (Wasserman and Faust, 1994; Carrington et al., 2005), game theoretic (Osborne and Rubinstein, 1994; Camerer, 2003), or computational representations (Macy and Skvoretz, 1998).

Social Classification

Scott L Washington, University of Chicago, Chicago, IL, USA

Abstract

Among social scientists, an emerging field of theory and research concerns the nature and workings of social classification. This topic has been highlighted by Starr (1992: pp. 267–274), among others, and it is now becoming a major point of interest across a variety of disciplines, including psychology, sociology, political science, history, and anthropology. The present article offers a formal definition of the topic. After emphasizing the compatibility of different perspectives, it identifies a number of themes common to the study of ethnicity, race, nationalism, caste, age, class, gender, and sexuality.

Among social scientists, an emerging field of theory and research concerns the nature and workings of social classification. This topic has been highlighted by Starr (1992: pp. 267–274), among others, and it is now becoming a major point of interest across a variety of disciplines, including psychology, sociology, political science, history, and anthropology. The present article offers a formal definition of the topic. After emphasizing the compatibility of different perspectives, it identifies a number of themes common to the study of ethnicity, race, nationalism, caste, age, class, gender, and sexuality.

A Definition

Fundamentally, *classification* refers to "the ordering or arrangement of objects" (Sokal, 1974: p. 1116) under a particular description. By nonexperts, as Sokal (1974: p. 1116) has noted, the term 'classification' is often used as if it were synonymous with the term 'identification'. But for scientific or analytical purposes it is helpful to distinguish between the two. Classification involves the creation of logical sets, or categories. Identification by contrast involves the assignment of objects to logical sets, or categories, "once such classes have been established by prior classification" (Sokal, 1974: p. 1116). The first is technically a precondition for the second. Indeed, it is only on the basis of a system of classification that we can 'identify' certain objects at all: a piece of furniture as being a 'chair', for example, "or a plant as being a 'buttercup'" (Sokal, 1974: p. 1116).

This point is all the more important to emphasize when it comes to systems of *social classification*. What is social classification? And what, if anything, is specifically social about it? In any system of social classification, properly speaking, every object is also a subject. The things classified are capable of classifying things. Using standard notation (where x represents a given set of objects; y, a given set of subjects; $\subset$, a term for inclusion; and $\wedge$, a logical operator meaning 'and'), we can define the topic formally:

$$x \subset y \wedge y \subset x$$

This once again is the defining characteristic of any system of social classification: that all of its objects are at the same time subjects, i.e., objects for whom objects exist.

It is essential to keep the definition being presented clear. Classification – or categorization – is by all accounts a basic process. It allows our minds to synthesize and retrieve information parsimoniously. But when a system of classification involves the ordering or arrangement of people (as opposed to plants, for example), something quite special occurs. An object may now object. The authors are now a part of the story being written, and the categories being used may no longer "aim to achieve [only an] economy of memory" (Sokal, 1974: p. 1116). Ordinarily indispensable to reasoning and communication, categories of thought, within systems of social classification, are simultaneously categories of being: 'human kinds', as Hacking (1995), addressing a similar point, has put it.

Here, it bears repeating, we are dealing strictly with systems of social classification. Other systems of classification (e.g., botanical, astronomical, or zoological systems) are technically *asocial*. The term 'natural' has also been used, but for at least two reasons it can be confusing. First, among philosophers, the term has come to be associated with debates over the existence of 'natural kinds'. These debates are concerned with the question of whether a particular system is artificial, or whether its categories are purely conventional. With respect to such debates, the present article remains agnostic. It is concerned only with the question of whether a system's objects are subjects. Second, many forms of social classification are presumed to be 'natural'. This is a fact, and for our purposes it cannot be ignored. Indeed, it is partly the task of a social scientist to explain how and why such presumptions come to exist. However awkward, the term 'asocial' remains logically consistent ($\sim p \neq p$), and it allows us to avoid many of the traps and controversies that have traditionally plagued a term like 'natural'.

It is also worth noting that we are not dealing with systems in which only some objects are subjects. Such is quite obviously the case with zoological systems. Indeed, although it might include *Homo sapiens*, every object in a zoological system (e.g., a starfish) is not also a subject, i.e., a being capable of using language in a self-conscious way. As a phenomenon (and not simply a phrase), 'social classification' refers once again to something very specific: the classification of people by people.

Psychological, Biological, and Sociological Perspectives

Within the social sciences, for the most part, the study of social classification has been defined by three perspectives: psychological, biological, and sociological. These perspectives belong to a division of scientific labor. They are in theory compatible.

Psychological Perspectives

For many psychologists, social classification has been a long-standing concern. One line of research can be traced back for example to Tajfel, who, in a now classic series of experiments, set out to document the impact of social classification under 'minimal' conditions. The results were quite revealing. The simple act of being classified, Tajfel et al. (1971) discovered, predisposed subjects to accentuate between-group differences, overestimate levels of out-group homogeneity, and develop forms of in-group favoritism, with respect to the allocation of resources as well as the evaluation of a person's conduct. These behaviors were not difficult to elicit. They emerged when subjects were classified temporarily and randomly, and even when the distinctions being introduced by the experimenter were trivial and previously meaningless (Tajfel et al., 1971). Though first published in the 1970s, the work of Tajfel remains influential, and it has since become the basis of an entire theory of intergroup behavior (Tajfel and Turner, 1986).

A more recent line of research – associated most prominently with the work of Fiske, among others (e.g., Macrae and Bodenhausen, 2000; Fiske and Macrae, 2012; Fiske and Taylor, 2013) – has focused on 'social cognition'. This body of scholarship has contributed greatly to our understanding of stereotypes, and through it psychologists have developed a better understanding of the cognitive dynamics behind the perception of groups and people (Hamilton and Sherman, 1996). Advances in neuroimaging have even allowed psychologists to link processes of impression formation to a specific area in the brain: mPFC, a dorsal region of the medial prefrontal cortex (Van Overwalle, 2009). For supplementary tasks (e.g., inferring goals and intentions), other parts of the brain also appear to be relevant, including the amygdala, the temporo–parietal junction, the posterior cingulate cortex, the inferior frontal gyrus, and the superior temporal sulcus, but much of the literature on processing strategies is still being generated (Fiske and Taylor, 2013). A subfield devoted entirely to the neural bases and correlates of social cognition (variously called 'social neuroscience', 'social neuropsychology', 'social-cognitive neuroscience', or 'social-cognitive neuropsychology') is now developing.

Biological Perspectives

As a topic, social classification has also been studied from a biological standpoint. Here evolutionary perspectives have been particularly insightful. As Kurzban et al. (2001) have argued, with respect for example to race, our disposition to classify each other is not unrelated to our development as a species. It can be understood partly as the byproduct of a cognitive machinery that evolved to detect coalitions and alliances. Though evolution might have selected for a basic capacity to encode a trait like gender or age (characteristics pertinent to our ability to reproduce), the same cannot be said of course for all forms of social classification, many of which were unknown to our ancestors. What is appealing about the Kurzban et al. (2001) model is that it can accommodate a phenomenon like race, a form of social classification which appears to have only developed in the modern era. It can also accommodate variation in the degree to which social distinctions become salient. As a hypothesis, the Kurzban et al. (2001) model suggests, a phenomenon like race is all the more likely to become salient when it meaningfully cues patterns of alliance.

Like a number of 'dual-process' theories (Fiske and Taylor, 2013: pp. 31–58), moreover, biological approaches bear a crucial implication: that a satisfactory account of our disposition to classify each other requires a study of the body as well as the mind. Not only after all do systems of social classification operate upon the body. They operate through it. This is why, under most conditions, the activation by a stimulus of a particular category seems 'automatic' (Macrae and Bodenhausen, 2000: pp. 96–102). In some contexts, it is true, a category might be used in a manner that is technical, deliberate, and controlled. But as a general description of the phenomenon, such an account can be misleading. With the exception of cases that are ambiguous or in some way unintelligible, for example, we simply *see* a 'woman'. The process by which we have identified the person as a 'woman' (a very complex process, involving the activation as well as the application of a particular category) is for the most part unconscious. Phenomenologically, it can only be said to exist after the fact.

The word 'see' might also be misleading. Traditionally sight has been treated as the 'noblest' of the senses (as Descartes once referred to it), but when it comes to the perception of objects – and especially the perception of subjects, which is to say, the perception of groups and people (Hamilton and Sherman, 1996) – not all cues are visual. This is not to deny the importance of visual cues. As diurnal creatures, hominids standing ultimately on their hind legs, the earliest humans developed their sensorium in such a way as to privilege cues that were visual. And, despite being the last of our senses to have developed fully, sight is broadly superior in its capacity to digest certain kinds of stimuli, allowing us to assimilate information from without at a far greater rate and distance than any other sense (Smith, 1986). As many of our own intuitions might suggest, however, the eye does not do its work alone, and the perception of groups and people is apt to involve all the senses of a socialized body. A person might not only *look* but *smell*, *feel*, or *sound* like a 'woman' as well.

Sociological Perspectives

Like biological perspectives, sociological perspectives offer a necessary and useful complement to psychological perspectives. For many researchers, at its heart, social classification is a cognitive act, a task performed quintessentially by individuals. But in a very real sense, sociologists have demonstrated, institutions as well as individuals can be said to classify. In the modern world, as Starr (1992), for example, has noted, states are inveterate classifiers. They make and enforce distinctions at a variety of levels, relying characteristically upon a variety of agents. "The design of classificatory systems is typically the prerogative of legislatures, … bureaucratic officials, and governing bodies …, whereas the [task of assigning people to a particular category] … belongs [properly] to … intermediary agents, such as … judges [or] 'street-level' bureaucrats, … who [are expected to] decide cases [or] certify [a person's] eligibility for benefits …" (Starr, 1992: p. 270).

It might seem as if the self-descriptions of people are irrelevant to the classificatory operations of a modern state. But, as Starr (1992: p. 270) is careful to note, statistical and

administrative systems vary with respect to how self-descriptions are handled. "At one extreme, some accept self-descriptions at face value; at the other, some classify and assign cases without attending [to such matters] at all…. Between the[se] two [extremes of course there] are countless variations…." To identify people racially, for example, the United States Census Bureau relied upon enumerators until 1970 (Petersen, 1987). Now self-reporting is the norm. Nor is the design of classificatory systems solely the prerogative of bureaucratic institutions. Financial institutions also classify people (Fourcade and Healy, 2013), along with clinical discourses and institutions of social control (Donnelly, 2000).

Institutions aside, sociological perspectives have also been instrumental in helping us grasp – what one might call, drawing once again upon Starr (1992) – the history and politics of social classification. How do categories come to be defined? Which distinctions are perceived to be legitimate? How and why do systems emerge, persist, change, or disappear? By exploring such questions, sociologists (as well as historians, anthropologists, political scientists, and others) have been able to show concretely that systems of social classification are by no means static, that people fight over who belongs where. This is an important point. To account for practices of social classification, sociological perspectives have taught us, it is not enough to understand how certain actors within a particular system perceive or make sense of each other. It is also necessary to understand how "social actors seek to shape the classificatory system and the pay-offs and risks of being categorized in specific ways" (Starr, 1992: p. 274). These pay-offs and risks are not only material. They can also be symbolic (involving for example the acquisition of a stigma) and emotional as well.

Paradigmatic Forms

While social classification is not always invoked explicitly as a topic, many scholars have already embarked upon a study of its forms. Mauss (1979[1924]: p. 32) famously called for a "catalogue of categories". A similar call might be made for a catalog of social categories, a survey of "all those which it is possible to know man has used". A provisional list would at the very least include ethnicity, race, and nationalism (Brubaker, 2009), of course, but also caste (which deserves to be considered alongside ethnicity, race, and nationalism), age, class, gender, and sexuality.

Age

In modern societies, a person's age is typically understood in chronological terms, and once codified it is likely to form the basis of an explicit policy. Legally, for example, a person might not become an 'adult' until the age of 18. In traditional or nonliterate societies, by contrast, a person's age is typically understood in maturational terms, and the transition from youth to adulthood (though marked at various points by rites of passage) tends not to be codified at all (Kertzer and Keith, 1984). While admittedly stark, such a comparison does have the merit of reminding us that, as Linton (1942) observed long ago, age can be studied as a form of social classification. This does not imply of course that age is just a state of mind. Like all organisms (and primates, in particular), human beings are mortal. They are born at a certain point and will die. But the life course of a human being can be divided into any number of stages, and – whether or not, for example, the notion of being 'middle-aged' is entirely unique to the contemporary period – the systems under which people are classified by an age can be said to vary historically and cross-culturally.

Class

The idea of studying class as a form of social classification social scientists have inherited partly from Bourdieu (1984[1979]: pp. 466–484), who in 1979 insisted that class struggles (i.e., struggles between classes) were ultimately inseparable from 'classification struggles' (i.e., struggles over the definition and meaning of classes). Whether distinctions like 'the upper class' or 'the middle class' are based upon a person's wealth, education, occupation, or lifestyle, the implications of such a view are clear. What a class 'is' (a question debated *ad nauseam* by scholars and laypeople alike) depends in each case on how it comes to be defined. Like any form of social classification, a class may be defined *analytically*, as a scientific concept, or *practically*, as a folk concept. A class may also be defined *officially*, as a concept which has been incorporated into the statistical and administrative practices of a modern state (Starr, 1992). The state's role in the making and unmaking of classes social scientists have explored with respect to a variety of cases, including, for example, *cadres* in France (Boltanski, 1987), *Angestellten* in Germany (Kocka, 1981), and professionals in countries like Britain or the United States (Szreter, 1993).

Ethnicity, Race, Nationalism, and Caste

A growing number of social scientists have now embraced the notion that ethnicity, race, and nationalism can be profitably studied alongside each other. Recently, in fact, an effort has been made to integrate each phenomenon into a single domain, a subfield defined loosely by a concern with cultural processes, social organization, and politics (Brubaker, 2009). This domain might be extended for our purposes to include caste, a form of social classification found principally in India (Berreman, 1972). Studying ethnicity, race, nationalism, and caste alongside each other does not require us to distinguish rigidly between each phenomenon. Indeed, as several academics have come to realize, attempting to establish "a sharp, clean distinction between [the] phenomena we ordinarily associate with race and ethnicity" can be quite unproductive (Brubaker, 2009: pp. 25–28), and it may reflect a concern that is more or less peculiar to the United States. Sometimes conceptions of race overlap with conceptions of ethnicity. Sometimes not. What is important scientifically is that each phenomenon can be studied, alongside nationalism and caste, as a form of social classification.

Gender and Sexuality

As many scholars have noted, gender is virtually 'ubiquitous' as a form of social classification (Maccoby, 1988: p. 755). Typically, conceptions of gender are dimorphic, with all cultures and known languages distinguishing at some level between males and females. But intermediate cases do exist. Socially, for example, a transgender person might be said to fall between

traditional conceptions of masculinity and femininity. Physiologically, a hermaphrodite or a pseudo-hermaphrodite might be said to do the same. Indeed, although rare, a person who is chromosomally male (XY) can have ambiguously female genitalia (androgen-insensitivity syndrome), and a person who is chromosomally female (XX) can have ambiguously male genitalia (congenital adrenal hyperplasia). Whether a female with Turner syndrome (XO) or a male with Klinefelter syndrome (XXY) might also qualify as an intermediate case remains a matter of dispute (Sax, 2002).

Like gender, sexuality can also be understood as a form of social classification, as a means of sorting people with respect to certain desires, behaviors, or orientations. Homosexuality from social scientists has perhaps received the most attention (Plummer, 1981). But homosexuality – as a label as well as a category of experience – has not always existed, and it is by no means the only manner in which a person might be classified sexually. In addition to 'homosexuality', for example, one may speak of 'heterosexuality', 'bisexuality', or 'asexuality'. With respect to sexual interests, more broadly, one may also speak of *zoophilia* (animals), *pedophilia* (children), *hebephilia* (pubescent males or females), *ephebephilia* (adolescent males or females), *androphilia* (adult males), or *gynephilia* (adult females). These are merely possibilities, any one of which (e.g., *pedophilia*) is liable to become entrenched as a category (e.g., 'pedophile').

Common Themes

Despite working in different fields, social scientists have addressed a number of themes common to the study of age, class, ethnicity, race, nationalism, caste, gender, and sexuality. Three, in particular, might be identified.

Membership

How is a person's membership in a particular category determined? Here like others (e.g., Brubaker, 2009: p. 26) we must distinguish between the *indicia* associated with a particular category and the *criteria* defining it. This distinction, it will be recalled, is perfectly consistent with the distinction between 'classification' and 'identification' (Sokal, 1974: p. 1116). Criteria are what allow us to classify a given object. Indicia are what allow us to identify it. For example, when it comes to determining a person's gender, properties like facial hair, clothing, the deepness of a person's voice, and breasts are typically indicia. Genitalia (e.g., a penis) and chromosomal pairings (e.g., XY) are typically criteria. When it comes to determining a person's age, similarly, properties like height and physique – including, among other things, muscle tone, hair, or the tightness of a person's skin – are typically indicia. Chronological markers (e.g., years or months since birth) are typically criteria.

Rarely are the criteria defining a person's membership in a particular category fixed once and for all. They are frequently a stake of struggles, and, as sociological perspectives have reminded us, the problem of establishing which criteria are legitimate is fundamentally political and historical (Starr, 1992). Nor of course is the existence of such criteria incompatible with the use of prototypes (Cantor and Mischel, 1979). A person might be French, as an example, but how 'French' he or she is perceived to be depends on how closely he or she approximates the prototype (and in some cases the stereotype) of a French person. Membership is often a matter of degree. Finally, it is by no means impossible for the same property to be used as a criterion in one context, while being used as an indicium in another. Conceptions of race in the United States and Brazil provide a striking example (Wagley, 1965). In the United States, where a person's ancestry is the reigning standard for determining who is black, skin color has been used as one of many indicia. In Brazil, where a different standard prevails, skin color has been used as one of many criteria.

The distinction between indicia and criteria is strictly analytical, and it can be applied once again to any form of social classification: age, class, ethnicity, race, caste, nationalism, gender, or sexuality. It can also help us understand how a person's membership in a particular category is 'managed' in a natural, everyday setting (a puzzle which has long preoccupied students of face-to-face behavior, particularly sociologists). An older person might attempt to look younger, for example, by manipulating in each case a particular set of indicia: wearing make-up, avoiding certain clothes, resorting to cosmetic treatments, or undergoing forms of plastic surgery. A comparable strategy might be adopted by a transgender person wishing to appear more or less masculine. This is partly what it means for a trait like gender or age to be, as some researchers have put it, 'accomplished' (West and Zimmerman, 1987; Laz, 1998).

Categories and Groups

What is the relationship between categories and groups? These terms are often used interchangeably, but it is important for social scientists to remember that, as Starr (1992: p. 281), Brubaker (2009: p. 28–34), and others have pointed out (e.g., Merton, 1968[1949]: pp. 353–354), a category is not a group. Technically, a *category* is a logical set, a class of objects that is only presumed to belong together. A *group* on the other hand is a self-conscious category, a class of subjects bearing a common point of identification. Under certain conditions, of course, a category of people might become a group, but we cannot assume beforehand that the process has already taken place.

No longer taken for granted, in fact, the 'groupness' associated with a particular category has been treated by many scholars as a variable (Merton, 1968[1949]: pp. 364–380; Starr, 1992: p. 281; Brubaker, 2009: pp. 28–34). Two approaches have typically prevailed. From one angle, researchers have attempted to understand how a group is objectively perceived. This is a problem of social cognition, pertaining chiefly to what psychologists call 'entitativity' (i.e., the extent to which a group is perceived by actors as an entity). From another angle, researchers have attempted to understand how a group is subjectively experienced. This is a problem of social cohesion, pertaining chiefly to feelings of solidarity (i.e., the extent to which a group is experienced by actors as an entity). Among Marxists, such concerns have traditionally assumed the form of debates regarding 'class consciousness'. But the problem of how a 'class-in-itself' might become a 'class-for-itself' is by no means unique to Marx or the making of a 'proletariat' alone. It is a theme common to all forms of social classification, a problem which can be said to exist whenever the objects grouped according to the logic of a particular system are subjects.

Stratification

How might social classification be related to stratification? At an interpersonal level, psychologists have shown (e.g., Locksley et al., 1980), social classification is a necessary but insufficient condition for discrimination, the differential treatment of people belonging individually to a category. At an institutional level, analogously, social classification can be understood as a necessary but insufficient condition for stratification, the ranking or arrangement of people into strata.

This point has been emphasized by Massey (2007: p. 8), who notes that "stratification begins psychologically with the creation of cognitive boundaries that allocate people to social categories", a capacity which appears to be hardwired into the human brain. Massey (2007) focuses in his analysis on race, gender, and class – each, a form of social classification which has functioned in the United States as a principle of stratification. Age too has functioned as a principle of stratification (Riley et al., 1972). But the importance of stratification to other forms of social classification remains an open question. Here it would be prudent to avoid the claim that, on its own, social classification is inherently or uniquely hierarchical. It is not. Though often linked to connotations of superiority or inferiority, social classification is nothing more (nor less) than a potential basis for stratification.

Conclusion

Jespersen (1964[1922]: p. 388) once referred to man as a 'classifying animal'. In any system of social classification, it might now be said, man also exists as a classified animal, an object who is equally a subject. For anyone in the social sciences, the question of what happens when a system's objects are subjects remains fundamental. This question is no less relevant to the study of age than it is to the study of class, ethnicity, race, nationalism, caste, gender, or sexuality. Like Molière's *gentilhomme*, in fact, we may soon realize that we have been speaking prose all our lives, addressing in different forms one and the same phenomenon: social classification.

Abstract

This article presents a brief overview of the social cognition approach that has developed in social psychology during the last few decades. We first provide a definition of social cognition, a description of its specific features, and a discussion of why social cognition should not be considered a mere extension of cognitive psychology. Then the article presents a short history of social cognition through the evolution of the representations of the social thinker. Finally, we describe the distinction between two modes of information processing that are of central importance in social cognition research.

Definition and Features of Social Cognition Approach

Social cognition can be defined as a domain of research studying human thinking and of its relationships with social behavior. More specifically, social cognition refers to the study of the processes by which people make sense of themselves and of others as well as of their social environment, and the implications of this thinking for social behavior (for detailed presentations, see for instance, Bless et al., 2004; Fiske and Taylor, 2007). Thinking should be interpreted here in a broad meaning: the cognitive processes (conscious and unconscious) that underlie the understanding of the social environment. Social cognition is thus interested in what information do people attend in specific situations, how they process, encode, and integrate this information with the stored knowledge, and in turn how these processes influence people's social perception, judgment, and behavior.

The approach of social cognition is characterized by several features. First, social cognition is interested more or less directly in social behavior. Even though it was primarily closely associated with social perception, social cognition would better describe an approach of social psychological phenomena than the study of a specific object. Most aspects of the social behavior can be, and are currently, studied within the perspective of social cognition. Social cognition investigates not only intraindividual phenomena (e.g., development of preferences, attitude; e.g., Gawronski and Bodenhausen, 2006), interactions (dyadic interaction as well as small groups, e.g., Nye and Brower, 1996), intergroup relations (Yzerbyt and Demoulin, 2010), but also the role of culture dimensions in cognitive and social functioning (Kitayama and Uskul, 2011). Moreover, a number of studies in social cognition deal with behaviors that would not have been intuitively categorized as social. For instance, research explores the extent to which performance on various tasks (at school, in institution, or in the lab) may be partially determined by the social context (e.g., Autin and Croizet, 2012; Steele and Aronson, 1995).

Second, social cognition is interested in the cognitive processes that underlie social behavior. Thus, social cognition research borrows models (e.g., associative network models of memory), concepts (e.g., attention, information processing) from cognitive psychology, and methods that have proved to be useful to measure cognitive functioning (e.g., reaction time, memory tasks, neuroimaging, psychophysiological measures; see Klauer et al., 2011). However, as we will see later, this does not mean that social cognition is restricted to the application of cognitive methods and models to the study of social behavior. Social inclusion (via the culture or the position is the social structure) is also considered as constraining cognitive processes (e.g., Kitayama and Uskul, 2011).

Finally, social cognition is interested in people's production of representations of their social environment. These lay theories or beliefs may concern any part of the social environment, the self being included. Their importance lies in the fact that they are supposed to guide judgments and behaviors. For instance, stereotypes, defined as lay beliefs about the psychological and physical attributes shared by the members of a social group, may have a strong impact on the way people judge, and act toward, members of the stereotyped group. Such beliefs can also influence the behavior of the very members of the group. As shown by Steele and Aronson (1995), Black students underperform White students on a verbal task only when their ethnic category (and thus the associated stereotype according to which Blacks perform less on verbal task than Whites) is made salient or relevant for the performance. These beliefs influence behavior beyond the stereotype domain. Recently, Job et al. (2010) demonstrated that theories people possess about the management of cognitive resources have a direct impact on their performance. People generally hold that mental control consumes resources that are limited. Thus, after an experience of mental control (e.g., an attempt to quit smoking or the reading of a complex research article), one should not be able to perform optimally until the resources have replenished. Job and colleagues found that it was indeed the case that participants who had previously exerted self-control in a first task underperformed in a subsequent task those who had not exerted self-control. However, the pattern was reversed for participants who were led to believe that, sometimes, mental efforts have energizing properties.

Social Cognition Is Not a Mere Extension of Cognitive Psychology

There are obvious overlaps between the processes that are studied in cognitive psychology and in social cognition. As already mentioned, both domains of research indeed relied on related concepts and methods. However, the processes studied

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24044-0

by social cognition research are hypothesized to be somewhat different because of the specificities of social objects (including persons).

In contrast to physical reality, which can be described relatively objectively, social reality (including others and oneself) cannot be observed directly and requires inferences and interpretations. One can evaluate the weight of a watermelon, the size of a car, or the material in which a ball is made with the use of an appropriate tool. Different persons in different contexts will certainly arrive at the same conclusion as long as the object and the measurement tools remain unchanged.

However, when we encounter a person, it is impossible to objectively know the person's feelings, his or her intentions and traits, whether one should trust him or her …. We can make up our impression on an individual extremely rapidly on the basis of some physical traits (e.g., Willis and Todorov, 2006), but this impression does probably not reflect reality. We have no possibility to objectively know whether this is the case. Moreover, not only are these features not directly observable, but we know that people are not always the same. People change, or show different features, depending on the situation, leading us to engage in revisions of our impressions. For instance, people do not show the same aspects of themselves when they are at work, when they interact with their mother, or with the person they love. Still more problematic, we know that we, as well as other people, intentionally attempt to influence the impressions we make. If you get an interview for a job, you will make effort to give 'a good impression' to the recruiter and thus show the positive aspects of your personality.

These examples may seem obvious when we consider the encounter of a new acquaintance. However, this also probably works for people we know (but generally meet in the same context). As a critical example, statistics indicate that a large part of the homicides (one-third in Canada in 2010; www.statcan.gc.ca; Hotton Mahony, 2011) are committed by a close relative, probably someone the victim could trust, and much more (70% according to 2010 Canadian statistics) by someone known by the victim.

We have deliberately focused our reasoning on the perception of others because people represent certainly the main 'objects' of our thoughts, judgments, and behaviors. It also applies to some extent to the perception of objects or ideas. They often possess symbolic values (motivational and emotional) that cannot be directly observed and are therefore inferred. For instance, if we consider digits and letters, they do not possess a priori strong social meaning. We can however observe that they do not possess the same value for an individual depending on his or her date of birth, occupation (digits should be more valued for a mathematician), name (e.g., Nuttin, 1985), or culture etc. Some of these properties emerge from the relations between these objects and the individual and have been found to constrain behavioral outputs (e.g., Jones et al., 2004).

The question addressed in this section was whether social cognition could be considered as a mere extension of cognitive psychology? The answer is thus clearly 'no.' The question could even be provocatively reversed: What is not social in cognition? Finally, it is difficult to think of any object that would not possess a social value. And, if it were the case, what would be the generalizability of processes related to such objects? Stated otherwise, in contrast to what is generally thought, it is possible to advance that processes highlighted by social cognition research reflect more the general rule than exceptions.

History of Social Cognition: Metaphors of the Social Thinker

Social cognition emerged from the development of social psychology in the late 1970s and was long considered as a branch of social psychology. Social psychology is assumed to have a long tradition of interest in cognition. Most of the pioneers in social psychology research (e.g., Solomon Asch, Fritz Heider, Kurt Lewin, or Muzafer Sherif) were strongly influenced by the Gestalt theory. As such, they espoused a holistic view of psychological phenomena. According to this view, an external stimulus has an impact on people's judgment and behavior through the subjective representation of the stimulus and not through its physical properties. What seems important in the determination of individuals' thought and behavior is the individual representation of the stimulus that is itself a product of the context in which this stimulus is perceived.

Nonetheless, it is the development of cognitive psychology – its models and methods – that gave the ultimate impetus to the emergence of social cognition. Social psychologists, who were convinced by this cognitive approach, developed a 'social cognitive approach.' The history of this approach can be traced in the early 1980s by three milestones. One of the most prestigious journals of social psychology, the *Journal of Personality and Social Psychology*, included an 'Attitudes and Social Cognition' section devoted to this approach in 1980. Two years later was published the first issue of another psychology journal, Social Cognition, totally dedicated to this domain. Finally, in 1984, Susan Fiske and Shelley Taylor published the first edition of *Social Cognition*, which was the first book of reference for researchers interested in the domain (see also Fiske and Taylor, 1991, 2007, for subsequent editions).

As we will see, the conception of the social thinker and thus social cognition has greatly evolved during the last few decades. This evolution can be illustrated by several metaphors (see Fiske and Taylor, 1991, 2007). The first metaphor presented the social thinker as a 'consistency seeker' (Fiske and Taylor, 1991). According to this view, the social thinker was an individual mainly motivated to maintain coherence in his cognitive system and in his social environment. Cognitive dissonance theory (Festinger, 1957) or balance theory (Heider, 1946) are perfect examples of this conception. Both theories propose that discrepancies between the cognitions in an individual system of thoughts are aversive. As a result, individuals are motivated to resolve these discrepancies and to restore consistency in the cognitive system. During the 1960s and 1970s, emerged the metaphor of the 'naïve scientist' (Fiske and Taylor, 1991) depicting an individual motivated to get an accurate perception of the environment. Research on attribution processes in which researchers attempt to explain how people attribute a cause to an event (Jones and Davis, 1965; Kelley, 1972) is particularly illustrative of this metaphor. Studies have however revealed that on many occasions individuals do not have the motivation or the processing resources necessary to engage in an extensive

processing of all the information available and that they rely on cognitive shortcuts in order to get an acceptable answer at a minimum cognitive cost (Tversky and Kahneman, 1974). From these observations, another metaphor was developed: the social thinker as a 'cognitive miser' (Fiske and Taylor, 1984). In this metaphor, the social agent is essentially motivated to preserve cognitive resources. The shortcomings in the perception of the social reality were thus essentially seen as consequences of a reduced investment in information processing. The work of Hamilton and Gifford (1976) on stereotype formation provides a good example of such a conception as well as an illustration of how in his early years social cognition applied cognitive theories and methods to social phenomena. Chapman (1967) had observed that people tend to overestimate the frequency of association between infrequent events. This effect was explained by the fact that infrequent events are salient and thus attract attention. Because they allocate more attention to these stimuli, people remember them more easily and thus overestimate their frequency when compared with less salient associations. On the basis of this work, Hamilton and Gifford (1976) provide evidence that these processes could offer an explanation for the association that White Americans made between Blacks and negative behaviors. As Blacks are a minority in the United States and that minority members are, by definition, more rare than majority members, they are distinctive and thus attract attention. The same being true for undesirable behaviors, which are rarer than desirable behaviors, people tend to overestimate frequency of undesirable behaviors performed by Afro-Americans.

However, the way that people process information, and ultimately engage in social behavior, is influenced by various motivations. Social interactions are indeed complex and, depending on their current goal, people are able to develop different strategies that will be served by different cognitive processes. Depending on the situation, people mostly want not to make a mistake (be accurate), to be accepted by others, or even to show their superiority over other individuals. Evidence supporting this line of reasoning contributed to the development of a new metaphor in which motivation and affect were given a central role: the 'motivated tactician' (Fiske and Taylor, 1991). This metaphor describes the social thinker is a social agent who possesses multiple goals and who puts in place different strategies in order to reach these goals.

In the last two decades, a growing number of studies has further shown that many of these processes could be automatically triggered by the context, with the individual being unaware of the processes that are implied in their social behavior and of its cause (Bargh, 1997). These studies revealed that concepts, stereotypes (e.g., Bargh et al., 1996; Devine, 1989), norms (Aarts and Dijksterhuis, 2003) and affect (Murphy and Zajonc, 1993) may influence thoughts, social judgment and behavior without participants being aware of this influence (e.g., Dijksterhuis and Aarts, 2010). These findings led to the development of the metaphor of the 'primed actor' (Fiske and Taylor, 2007). In this view, the situation provides the individual with many cues that can be unconsciously and automatically used to guide cognitive, affective, and behavioral outputs. Although relatively automatic, these processes need not to be considered as totally innate. There is now growing evidence that culture, conceptualized in a broad (e.g., Westerners vs Easterners) or in a narrower meaning (e.g., social status), shapes and regulates the way our cognitive system operates, leading to pay attention to different aspects of a situation, to develop different goals, representations, and to make different inferences (Kitayama and Uskul, 2011; Snibbe and Markus, 2005). Thus, social cognition research now tends to describe the social thinker as an individual unconsciously governed by cognitive processes that possess strong motivational and emotional components, and that are partially shaped by culture. A last emerging aspect in recent development of social cognition is the increasing importance of the body in the way we think about, and interact with, our social environment (e.g., Niedenthal et al., 2005).

Social cognition is probably currently one of the most prominent and still promising domains of research in social psychology. However, it is worth noting that interest in social cognition has spread over various domains of study of the human thought and behavior. Social cognition is currently widely studied in related domains, such as developmental psychology, psychopathology, and neurosciences (e.g., Cacioppo et al., 2002).

How Do People Think About Social Issues?

The Different Steps of Information Processing

Four main steps of information processing can be broadly distinguished. First, perceptual inputs are received. Then, information from these inputs is encoded and stored in memory. Finally, this stored information is potentially used to guide behavioral outputs. The processing of the social information does not depart from this general sequence. However, social cognition research is interested in how these different stages are influenced, or constrained, by the social context.

Attention is expected to play a crucial role. Because we cannot attend to all the information provided by the situation, our attention is directed toward information that should thus be treated more deeply, which have the potential for more consequences on subsequent judgment and behavior. Which information will receive more attention? A first answer is information that is particularly salient (e.g., infrequent events, abrupt onsets). However, attention can also be attracted by situational features that serve the current goal of the individual. For instance, participants who are made thirsty by eating salty sweets pay more attention than nonthirsty participants to objects related to drinking behavior (e.g., bottle of water, glass; Aarts et al., 2001).

Another important basic goal of human beings is the preservation of one's own physical safety. As a result, in intergroup context people tend to first allocate more attention to outgroup members, and then to the ingroup (Ito and Urland, 2005). Early attention toward outgroup members would serve a protection motive, that would then turn in attention to ingroup members in the absence of real threat. In other words, people pay more attention to information that is particularly relevant for them and their goals. Therefore, this is no surprise that information that is directly related to the self (e.g., one's own name) attracts attention and is even difficult to ignore (e.g., Alexopoulos et al., 2012).

Attention will generally favor encoding and integration of the information in the stored knowledge about objects, individuals or situations. However, information will be more easily encoded (and integrated for future use) to the extent that it is consistent with the knowledge already stored in memory. As a result, even though blatantly inconsistent information attracts more attention than information consistent with our prior knowledge (because of the revision of the action plan that it may imply for the individual), this information should be recalled to a lesser extent if people do not want or cannot make extra effort to integrate it. Most of the time, people cannot afford to integrate all the incoming information because of a limitation in processing resources and time constraints. Thus, in conditions of limited processing resources, information that is consistent with prior knowledge will be easier to encode (as it requires less attentional capacity), better integrated, and more easily retrieved (e.g., Macrae et al., 1993).

Ultimately, what is stored in memory and activated will guide the behavior of the individual. Of course, only a subset of the information stored in memory will play that role. The behavior will be guided by information that is 'accessible.' Accessibility refers to ease with which one can access to a specific piece of information (e.g., concept) in the cognitive system. This accessibility is a function of the frequency and of recency of the activation of the information. Although accessibility influence the likelihood to engage in a given behavior, this does not mean that the individual will necessary engage in that behavior. Several factors, such as normative pressure or other aspects of the situation, may reduce the likelihood that the activation of such behavioral tendencies translates into overt behavior (Macrae and Johnston, 1998; Strack and Deutsch, 2004). For instance, Devine (1989) showed that low- and high-prejudiced people share the same knowledge about the stereotype of Afro-Americans in the USA, that they use it when it is unobtrusively activated. However, she found that in contrast with high-prejudiced participants, low-prejudiced participants do not use their stereotypical knowledge when asked to explicitly describe their thoughts about Black Americans.

Dual-Process Models of Information Processing

The sequence of information processing that has just been described is general. However, and as the research by Devine illustrates, this sequence could lead to diverging results as a function of the mode of processing on which individuals rely. There is a general agreement in social cognition to consider that people rely on two different modes of thinking. Theoretical descriptions of these two modes of thinking are referred to as 'dual-process models' of information processing (see Evans, 2008). The first mode (called, among others, 'system 1,' 'heuristic,' 'impulsive,' or 'associative') is fast, relatively automatic, requires few processing resources, and allows to get a rapid answer to our environment, whereas the other mode of processing (called, among others, 'system 2,' 'systematic,' 'reflective' or 'propositional,' respectively) is slow, controlled, and consumes cognitive resources.

The first (fast) mode of thinking is considered to be the most commonly used by the social thinker (Bargh, 1997) because it satisfies people's constraints of minimizing their efforts and of providing them fast with an acceptable answer. The processes involved in this mode of thinking are various. However, they globally work the same way: people rely on a subset of the available information that will allow them to develop mental shortcuts to arrive at a judgment or at a decision. For instance, people can rely on their affective feelings in order to infer whether they like something or someone (Schwarz and Clore, 1983) or whether their current thoughts about this object can be relied on without engaging in a costly examination of the specific features of the object or person. In a related vein, people estimate the frequency of an event from the ease with which they can recall exemplars of this kind of event, relying on the 'availability heuristic' (Tversky and Kahneman, 1974). More general knowledge structures can be used to develop rapid judgment. These structures are learned through socialization and can become highly automatized, and sometimes activated automatically upon the perception of the object. As an example, stereotypes can be automatically activated in memory upon the perception of a person, and then guide the perception of the person and interpretation of his or her behavior (Devine, 1989). For instance, the identification of a person as a woman could automatically lead to expect that this person is dependent, not skilled in math, romantic, etc. This last example illustrates a negative aspect of this mode of thinking. However, the same processes can also explain why experts are sometimes able to provide a fast response to a problem.

These cues can be used even when people are not aware of such use. The absence of awareness can take two different forms. People can process the stimulus consciously (e.g., they consciously perceive that the person is a woman), yet do not notice that this categorization will have any impact on their judgment or behavior (e.g., they judge the person as having poor math skills, and not suitable for a job of engineer). This kind of processes is referred to as 'postconscious.' The number and the variety of cues (stimuli) that are (nonconsciously) used as a basis of judgment and behavior are very large. In addition to categories that are particularly salient or socially meaningful (e.g., color of the skin, gender, age) many other cues are used without people knowing that they use them. In the domain of person perception, people can rely on the form of the target's face (Zebrowitz and McDonald, 1991), the degree of pupillary dilatation (Niedenthal and Cantor, 1986), the number of previous encounters with the target (Zajonc, 1968), or the experienced temperature (Williams and Bargh, 2008). Particularly illustrative of this point are the findings showing the identification of the valence (positive vs negative) of an extreme emotion experienced by another person requires the use of the physical position of the body. Interestingly, whereas they efficiently use this information (and not facial expression) to make their predictions, people still believe that they base their judgments on facial expressions (Aviezer et al., 2012).

On some occasions, people can even not be conscious of the information that influences them. These 'preconscious processes' are typically studied with the use of subliminal priming (i.e., a procedure aimed at presenting stimuli unconsciously). Concepts, stereotypes but also goals can be activated preconsciously, with an influence on information interpretation, judgment, and social behavior (Bargh et al., 1996; Devine, 1989; Dijksterhuis and Aarts, 2010). For instance, the

nonconscious activation of the stereotype of Black people (associated with hostility for American participants) leads people to subsequently interpret the behavior of a target as being more aggressive (Devine, 1989) but also to behave more aggressively (Bargh et al., 1996).

In dual-process models, this mode of processing is contrasted with a more controlled one in which people consciously engage in various strategies in order to reach their goal. For instance, if individuals want to get an accurate perception of a situation, they may attempt to take into account the available information and integrate it in order to take the right decision. This is typically the mode of processing that we attempt to use when we have an important decision to take. This mode of thinking is associated with voluntary control, effort, and rationality, and is closer to the lay people's belief concerning the way they think about their social environment. As already mentioned, this belief is however not true. It is indeed difficult to think of a situation in which people would be totally free from pre- or postconscious processes. For instance, recent studies suggest that even the operation of highly controlled processes (executive control) can be partially influenced by preconscious processes (Marien et al., 2012).

When Do People Rely on One or the Other Mode of Thinking?

Social cognitivists consider the fast mode of thinking as the default option because it satisfies resources and time constraints. The relevance of the cues (and the related rules) that are later used in the fast mode is learned through socialization processes and practice. Many activities require voluntary control and consciousness to be learned, but are automatized through experience, to be then executed on the basis of the simple presence of significant cues. A classical example of these processes is when people learn to drive. During the first driving lessons, people should pay attention to many aspects that will be later processed automatically. Thus, one can pass from the slow system to the fast one through practice and experience.

In contrast, people engaged in the fast system can sometimes opt for the slow one. This seems to occur typically in two types of situation. First, there are situations in which the fast system is expected not to provide an acceptable answer regarding the situational requirements. For instance, the resolution of a mathematical problem or the understanding of a complex psychological theory requires that one deliberately control our attention and thoughts. Then, people also attempt to regain control on the way they process the situation when inappropriate decisions, judgments, or behaviors are perceived as having potential important consequences for the individual. For instance, if you envisage buying a new apartment, you should think that it would be wiser to take your time to take into account all the information you can bring, and to examine it carefully before you decide to invest all your savings. In a similar vein, if you want to make a good impression on someone (for a job, for the loved one), you would probably attempt to control your behavior in order to avoid any reaction that would lead to a negative impression. This is not to say that it would lead to more efficient use than relying on other (fast or unconscious) processes (Wegner, 1994; Dijksterhuis, 2004), even though we believe so.

There is great agreement on this distinction between two modes of thinking in social cognition research. There are however several aspects that are still debated. First, depending on the theoretical positions, the two modes of processing are hypothesized to function in parallel whereas for others these two models could not take place at the same time, and should thus be conceived as sequentially organized. A related question is the possible interactions between these two modes of processing, especially when they are conceived as working in parallel (e.g., Gawronski and Bodenhausen, 2006; Strack and Deutsch, 2004). Another question is related to the neuroanatomical structures that support these modes of thinking. Depending on the model, both modes rely on the same structures whereas they refer to different pathways for other theorists.

Conclusion

After three decades of study, social cognition has become a vast domain of research that brought many enlightening findings – all of which could not be brought out in the present article due to space limitations – about the way we construct social reality (see, for more detailed presentations, Bless et al., 2004; Fiske and Taylor, 2007). In the same time, these findings have strongly modified the picture of the social thinker. This picture is far now more complex than is was still few years ago, integrating intra- as well culture-related processes. These evolutions of social cognition underline its great explanatory power as well the potential for promising discoveries that researchers should undertake in this domain.

Abstract

Social comparison theory deals with self-evaluation of abilities, opinions, and other personal attributes through comparing the self with others. We outline the original theory and the methods used to study it empirically. We discuss how individuals may compare upward or downward and may assimilate their self-evaluations toward or contrast away from the comparison person. We close with a discussion of implications for education, health, and happiness.

Social comparison occurs when an individual compares himself or herself to another person. The dimension on which the comparison is made can be almost anything – attractiveness, tennis skill, wealth, etc.

The comparison might be sought deliberately, might occur in a chance encounter, or might be forced upon the person by the social environment. It is not social comparison when one compares one person to another, as in comparing one neighbor to another; the individual making the comparison must be included in the comparison for it to fit the commonly accepted definition of a social comparison. It is not a social comparison when one compares oneself at Time 1 to oneself at Time 2; this is a temporal comparison (Albert, 1977).

The Original Theory

Leon Festinger's (1954) paper, *A Theory of Social Comparison Processes*, still serves as the basic formulation, although there have been many additions and revisions. Festinger argued that it is necessary for people to know what they are capable of doing and to hold correct opinions about the world. Sometimes people can perform a physical reality test on their abilities and opinions, but that could be dangerous, inconvenient, or impossible. For example, if individuals want to know whether they can swim across a swift river, they could simply try it, but that could be dangerous. If it is a person's opinion that the Russian Revolution would not have occurred without V.I. Lenin, there is simply no physical reality test for the truth of that opinion. Consequently, people often seek *social reality* rather than physical reality for their abilities and opinions, and that social reality is obtained through social comparison. An important difference between opinions and abilities in Festinger's theory is a *unidirectional drive upward* for abilities but not for opinions. Regardless of the ability, people would generally like to have more of it than other people have. With opinions, however, people feel confident when they have the same opinions as others. Thus, all the members of a group can be satisfied when they have the same opinion, but not when they have exactly the same level of ability. The central argument of the theory is that we need to compare with similar people in order to achieve a precise estimate of our abilities and the correctness of our opinions. Consequently, we will try to change others or ourselves in order to achieve similarity, and we will reject others if similarity with them cannot be achieved.

Although the original theory dealt with opinions and abilities, most of the research done after the 1950s has been on abilities or ability like personal attributes. The original theory focused on the accurate evaluation of abilities/opinions, but later research has focused less on the accuracy of evaluation and more on the self-esteem implications of evaluation. We do not just want to know how charming we are; we want to know that we are very charming indeed. Wanting to know certain things about ourselves influences both the comparisons we make and how we interpret or construe those comparisons.

Methods for Studying Social Comparison

The three major methods for studying social comparison are 'selection' approaches, which examine the characteristics of the people with whom individuals choose to compare; 'reaction' approaches, which examine individuals' emotional or cognitive reactions to comparison information; and 'narration' approaches, which examine individuals' self-reports of comparisons made (Wood, 1996). Each of these will be examined below.

The Selection Approach

Individuals are given the choice of two or more comparison targets that differ in theoretically important ways. The choices they make (and related data) provide clues concerning social comparison motives. The first notable example, known as the 'rank-order paradigm,' was introduced to study the unidirectional drive upward. Experimental participants were tested on a (fictitious) desirable or undesirable personality trait, such as 'intellectual flexibility' and were told that they occupied the middle rank in a group of several other participants tested at the same time. Participants were given their own (fictitious) score on the test, as well as the rank of each of the other participants, and were told that they could be shown the score of one other person in the group. The rank of the person participants chose to see could be of someone better off than

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24026-9

themselves (known as an 'upward comparison') or worse off than themselves (a 'downward comparison'). In most of the experiments using this method, participants chose to see the scores of those just above them in the rank order. That is, they wanted to compare their scores to slightly better scores (Wheeler, 1966), supporting the similarity hypothesis and the unidirectional drive upward.

The Reaction Approach

Individuals are presented with social comparison information, and their responses to that information are measured. In what is known as the Mr Clean/Mr Dirty study, job applicants casually encountered another applicant whose appearance was either socially desirable (dark suit, well-groomed, and confident) or socially undesirable (torn and smelly clothes, poorly groomed, and confused). Those participants who encountered Mr Clean showed a decrease in self-esteem measured a few minutes later, whereas those who encountered Mr Dirty showed an increase in self-esteem (Morse and Gergen, 1970). In this research, participants contrasted themselves against the other job applicant, but this is not always what happens. As we will discuss below, sometimes people will assimilate their self-judgments to the comparison standard.

The Narrative Approach

This nonexperimental approach attempts to measure the comparisons that people make or have made in their everyday lives. At the most basic level, participants are sometimes asked whom they have compared themselves with in the past. This places too great a burden on memory, however, and a better method is the *Social Comparison Record*, a diary recording of all comparisons as they occur over a period of 2 weeks, including the dimension of comparison, the direction (e.g., upward, downward), relationship to the target, and mood before and after the comparison (Wheeler and Miyake, 1992). When participants were experiencing negative affect, they made upward comparisons. In contrast, when the same participants were experiencing positive affect, they made downward comparisons. Such a result is consistent with *affect–cognition priming* models in which affect primes (make ready and available) cognitions about the self that are congruent with the affect. Experiencing negative affect primes a person to have negative thoughts about the self and thus to see others as superior to the self, leading to a contrastive upward comparison and further feelings of inferiority and negative affect. This research also showed that there was generally a negative emotional response to upward comparisons, and a positive emotional response to downward comparisons. Finally, downward comparisons were more frequent than upward comparisons.

Free response measures are also narrative in approach. These are spontaneous statements, usually made during the course of an interview or conversation, implying comparisons. Wood et al. (1985) reported that breast cancer patients made many free response comparison statements, most of which seemed to indicate downward comparison, such as "I think I am coping a little better than these other women."

The Changing Face of Similarity

Festinger (1954) argued that we must compare with similar others in order to make accurate self-evaluations, but he was not clear about the kind of similarity that was important. At first, investigators focused on (1) similarity on the dimension under evaluation, as we described for the rank-order paradigm. A person wanting to evaluate his or her speed in messaging would compare to someone who is slightly faster. This really does not tell you how fast you are compared to all other people, or whether you should take up thumb work as a profession; it merely tells you that you are or are not faster than the other person. Moreover, there is circularity in saying that we should compare to similar others – if we already know they are similar, why compare with them? To deal with this problem, Goethals and Darley (1977) proposed the 'related attributes' hypothesis. A person should compare to (2) someone who is similar to him or her on attributes related to and predictive of the dimension to be evaluated. Thus, the person should seek a comparison standard who is equally young and dexterous and who spends the same amount of time each day messaging. The person ought to perform about the same as this comparison standard, and if the person outperforms the standard, they will feel that he or she has an unusual ability. In short, the related attributes hypothesis does allow us to get a better understanding of our capabilities and to choose appropriate competitors.

A later attempt to untangle the question of similarity was based on the realization that Festinger was not so concerned with whether one labeled oneself as having low or high ability, but rather with the action possibilities of having a given level of ability. For example, one of the questions addressed by Festinger's theory was 'Can I do X?' Can I swim across the river? Can I complete a college degree? Can I have both a family and a career? One way to answer such questions is to compare oneself to someone – called a proxy – who seems to have a similar level of ability and who has already succeeded at the task (Wheeler et al., 1997). If people seem to have the same amount or more of the ability required as the proxy does, they could conclude with some confidence that they could also perform the task. There are two ways that people can be confident that they have as much of the underlying ability as the proxy: (1) they previously have competed directly against the proxy and have performed as well as the proxy at his best, or (2) they have observed the proxy performing and are similar to the proxy on attributes related to the ability. In both cases, they have established with some degree of certainty that they are similar in ability to the proxy and thus have the same action possibilities. This allows them to pursue the task with some confidence that they, like the proxy, have the right stuff to succeed. We believe that this is the correct interpretation of why Festinger argued that the comparison target should be similar in order for accurate self-evaluation to occur. Individuals want to evaluate their ability to perform some action successfully, and they determine this by comparing with a proxy of similar ability who has already performed that action.

Lockwood and Kunda (1997), who exposed first year and fourth year university students to a newspaper article about a superstar fourth year student, illustrated this nicely. Participants and superstar were matched on the related attributes of

gender and academic major. In a control condition, participants did not read about any target. The dependent variable was self-ratings on 10 adjectives related to career success. The first year students, with time to work toward the success of the superstar, gave themselves high self-ratings, but the fourth year students, who had missed the chance to be a superstar, did not. The first year students used the superstar as a proxy to determine what they might achieve in the future.

Opinion Comparison

As mentioned earlier, comparison of opinions has not been as actively studied as abilities and traits. This is somewhat surprising because persuasion has been an intense area of social psychological research for decades. The likely explanation is in everyday life, persuasive messages most often involve not just learning the source's (comparative) view but also being exposed to arguments. To identify the pure 'comparison effect,' researchers need to strip the comparison process away from the persuasive content, but this limits ecological validity.

Despite this matter, the related attribute approach devoted some attention to opinion comparison. First, in contrast to Festinger who treated opinions generically, Goethals and Darley distinguished between belief and value opinions. Beliefs refer to verifiable facts, whereas values are personal preferences. Comparisons with similar others on related attributes, such as background and general worldview, are of most utility for value assessment. For beliefs, however, someone who is dissimilar on related attributes was hypothesized to be more useful because they provide a different perspective to 'triangulate on' the truth.

The more recent triadic model (Suls et al., 2000) concurs with Goethals and Darley's prediction about values, but to assess facts, people should prefer to compare with someone who is superior on related attributes (conferring more expertise) not just dissimilar per se. Since few facts are completely value-free, however, someone who has more expertise and also shares the same basic values (i.e., worldview) is probably most preferred. The triadic model refers to such a person as a 'similar expert,' and illustrated by the finding that gay men are more likely to adopt safe-sex practices when they are advocated by someone who is both more knowledgeable and shares their sexual orientation (Kelly et al., 1991).

The new model is called 'triadic' because it adds a third kind of opinion comparison, which concerns predictions about affective responses to future situations (e.g., will I like that new film 'X'?). I can predict my future response with some confidence by learning about the response to 'X' of a proxy who has already viewed the film. The proxy should be considered appropriate if he/she shares related attributes or past pattern of agreement with respect to other films. Suls et al. (2000) presented supportive empirical evidence for the triadic model predictions.

Assimilation and Contrast

Until the 1990s, most students of social comparison theory believed that comparison always led to contrast with the comparison target. That is, an upward comparison (with someone better) lowered a person's self-evaluation, and a downward comparison (with someone worse) raised the self-evaluation, as shown in the Mr Clean/Mr Dirty study. There was even a subsidiary theory called 'Downward comparison principles in social psychology' that argued that when people are psychologically threatened they will deliberately seek out someone worse to compare themselves to in order to relieve their distress (Wills, 1981). This theory was quite influential during the 1980s until accumulating evidence caused it to be abandoned. The basic problem with the theory is that when people are psychologically threatened, they are more inclined to see others as superior to themselves and would have difficulty in finding and using downward comparison targets. We discussed previously the research showing that when people are experiencing negative affect, they are more likely to make upward comparisons rather than downward comparisons (Wheeler and Miyake, 1992). Presumably, this happens because negative affect causes people to perceive themselves negatively and to perceive most other people as superiors to themselves. In short, although downward comparison does generally make people feel better, people who are distressed or threatened find it difficult to find and use downward comparisons.

While believing that comparison usually led to contrast, researchers were aware that the rank-order studies, among others, had shown that people usually compare upward. If comparing upward leads to contrasting feelings of inferiority, why would people do it?

Upward Assimilation Theory

Buunk et al. (1990) asked married individuals and cancer patients to indicate how often they experienced both positive and negative emotions when comparing upward and downward. In the case of cancer patients, the downward comparison target was doing worse with the cancer, and the upward target was doing better. In the case of married individuals, the downward comparison was a marital relationship worse than that of the respondent, and the upward comparison was better. For both cancer and marital quality, the direction of comparison did not dictate how often positive or negative affect was experienced – both directions had positive and negative aspects. The paper was important in showing that upward comparison does not necessarily lead to negative affect, but can also lead to feeling inspired, comforted, happy, and pleased. Collins (1996, 2000), one of the authors of the paper just described, undertook a thorough review of the positive effects of upward comparison and proposed a theory of upward assimilation. She argued that upward comparison could lead to either contrast or assimilation depending upon whether the comparison was construed as showing similarity to, or difference from, the comparison standard. People are more likely to construe themselves as similar to upward targets if they *expect* to be similar to the upward targets. In the rank-order paradigm study discussed above (Wheeler, 1966), participants who expected to be more similar to the person above them in the rank order than to the person below them choose to compare with the person above them. The interpretation was that they had

assumed similarity upward and wanted to confirm that they were indeed similar to that person. According to Collins, some variables that might lead to such expectations of similarity to upward targets are (1) high self-esteem, (2) shared distinctiveness with the upward target (such as belonging to the same club), and (3) the direction of comparison. People with high self-esteem generally think that they are as good or better than others are and so should expect to be similar to upward targets. People who share distinctiveness with the upward target draw the conclusion that if they are similar on one distinctive thing, they are probably similar on performance as well. People who are comparing upward have higher expectation of similarity than those comparing downward because of the unidirectional drive upward. Of course, other variables in addition to self-esteem, shared distinctiveness, and the direction of comparison, such as similarity on related attributes (Goethals and Darley, 1977), might lead to expectations of similarity on performance. Whatever leads us to expect similarity and thus to construe that we are similar to upward comparison targets, the result is an increase of some sort in our own self-evaluations. For example, an academic person with six publications might compare with another academic person with 10 publications. If individuals construe 6 publications to be similar to 10 publications, they will conclude that they are solid (and satisfied) members of that class of academician with 6 to 10 publications. If they construe 6 publications and 10 publications to be dissimilar, they will feel inferior to those with 10 publications. Nosanchuk and Erickson (1985) provided a dramatic example of upward assimilation among bridge players. Players indicated that in a variety of situations, they would prefer to compare themselves to players of similar ability. However, when they named the particular players they would compare with, these players turned out to be objectively better players with more master points. Thus, the bridge players had assimilated their ability to the ability of the superior players.

Upward assimilation is an increase in one's self-evaluation because of making an upward comparison. Although this has often been obscured, it is not simply a happy feeling or feeling positive about the future but is a perceptual change in one's self-evaluation. Collins (1996, 2000) noted that downward assimilation is not likely to occur, because of the unidirectional drive upward. Our need to be better and to improve works against downward assimilation.

The Selective Accessibility Model

Mussweiler (2003) proposed a theory in agreement with that of Collins (1996, 2000) but using concepts from the social cognition literature and giving more detail about the mechanisms involved in social comparison. At the moment of exposure to social comparison information, a person makes a tentative judgment of similarity or dissimilarity to the comparison target. Salient features (such as gender, race, or age) of the comparison target determine this judgment. Then the person searches for information consistent with the preliminary judgment of similarity or dissimilarity. Whether one searches for similarity information or dissimilarity information, one is likely to find it because our view of ourselves is remarkably rich and complicated. It is easy to find information whether one is similar or dissimilar to another person. That information then becomes selectively accessible when we make judgments about ourselves. If we have searched for information that we are similar to the standard, we are likely to assimilate our self-evaluations toward the target. If we have searched for information that we are dissimilar to the target, we are likely to contrast our self-evaluations away from the target.

The selective accessibility model (SAM) is elegantly simple and explains a wide variety of empirical results. Contrast is more likely if the standard is extreme or unattainable, or if the standard belongs to an out-group, both of which would lead to an initial hypothesis of dissimilarity. Assimilation is more likely to occur if there is psychological closeness with the standard, which would lead to a search for similarity. If people prior to comparison are asked to point out similarities between two drawings (i.e., procedural priming), they subsequently will more likely assimilate to the comparison standard than if they have pointed out differences. A shortcoming is that the SAM does not explicitly recognize that self-protective concerns may bias comparisons. For example, there is abundant evidence that people assimilate upward, but there is almost no evidence of downward assimilation. The SAM would argue that upward and downward assimilation are equally likely. In fairness, however, one could modify the SAM slightly and state that one would not search for similarity with a downward standard because of self-esteem concerns.

Mussweiler and colleagues have performed numerous experiments that support the SAM. However, an unfortunate aspect of this research is that adequate control groups are rarely used. Conditions that should lead to assimilation are compared to conditions that should lead to contrast. When there is a difference, the researchers argue that they have confirming evidence for the SAM. However, without a control group that is not exposed to any comparison target, there is no way to know whether assimilation has occurred, contrast has occurred, or both have occurred.

Mussweiler makes an important distinction between subjective and objective self-evaluation. An upward comparison standard has two effects. First, it produces a search for similarity to the standard and thus makes accessible knowledge that the self is similar to the high standard. Second, it serves as a reference point (or scale anchor) for making a subjective self-evaluation. The comparison standard may alter the interpretation of subjective rating scales ('very intelligent' may be interpreted differently in the context of a professor than in the context of an infant). These two influences work in opposite directions when making a subjective judgment. If one compares to an intelligent standard (say, professor) one may search for and find information about the self that indicates high intelligence. If then asked to indicate one's intelligence on a subjective scale from 1 to 10, one may assume that 10 is close to the professor's intelligence and so may contrast oneself away from this endpoint despite having accessible information that one is intelligent. Whether assimilation or contrast occurs depends upon the relative strength of the selective accessibility and the reference point effects. On the other hand, if objective self-evaluations are used, there is

no reference point effect to worry about. Objective self-evaluation questions pertaining to intelligence might inquire about the amount of time taken to solve a crossword puzzle, or the number of unknown words encountered in a typical book. Because of the ambiguity of subjective self-evaluations, Mussweiler always uses objective self-evaluations.

Assimilation and Contrast in Education

Social comparison tendencies should be strong in education settings when students compare their performance with others in their class or school and draw conclusions about their academic ability. The frog pond effect (Davis, 1966) refers to the fact that students attending highly selective schools have lower academic self-concepts than those attending nonselective schools (holding academic ability constant). This has been demonstrated in elementary, middle, and high schools across more than 40 countries (Seaton et al., 2009). The explanation is that people compare with those around them and ignore the larger context. Students in a highly selective school ought to have high academic self-concepts; after all, they have earned a place in the highly selective school. However, when they compare themselves with their classmates, they find that they are not superior in ability, and they ignore the fact that their classmates are near the top of the ability continuum. Zell and Alicke (2009) have referred to this contextual neglect of general comparison information as the 'local dominance effect' and have shown that being the best or worst performer in a group of five people influences self-evaluation more than the information about one's standing among 1500 other individuals. During early development, we compare with family members and small groups of peers, and this continues to be a salient mode of self-evaluation as we mature.

In an international collaboration, Huguet et al. (2009) conducted a highly detailed study of social comparison in French public schools. They showed that the frog pond effect was indeed due to the students' perceived relative standing in the class; those who perceived themselves as having relatively low standing had lower academic self-concepts. Thus, contrastive social comparison caused the frog pond effect. The students also named those classmates with whom they chose to compare grades. They named classmates who on average had slightly better grades, and to the extent that they did so, the students had higher academic self-concepts. Thus, assimilative social comparison occurred independently of contrastive social comparison. The assimilative comparison related to comparisons the students deliberately chose to make, whereas the contrastive comparison related to the comparisons forced on the students by the class average. Of the two effects, the reduction in self-concept due to contrastive comparison was much larger than the increase in self-concept due to assimilative comparisons.

Although students named objectively superior classmates as the ones they usually compared with, they believed that they were similar to these superior others, precisely the results of the Nosanchuk and Erickson (1985) study of bridge players. They had assimilated their own ability upward.

Chronic Illness and Social Comparison

Earlier we mentioned the application of comparison processes to the coping of cancer patients. As illness creates uncertainty and stress, social comparison can play a role in coping and adjustment of medical patients. There have been many descriptive–correlational studies and a smaller set of experiments using the reaction methodology to explore the role of social comparison among medical patients (e.g., Stanton et al., 1999). There are two aspects of illness that can be compared: (1) the severity of the illness and (2) how well one is coping with the illness. A recent literature review (Arigo et al., 2012) concluded that identifying or having an actual contact with someone who is coping better tends to be beneficial for patients, while contrasting or being exposed to information about someone with more severe illness tends to be beneficial. In contrast, downward comparisons about coping and upward comparisons about illness severity seem to be unhelpful. The descriptive–correlational research, based on narration and selection methods, provides the most consistent evidence. Making strong claims from these trends is premature, however. As in the basic research literature, few experimental studies included no-comparison controls to be able to determine whether assimilation or contrast has occurred or both have occurred. The few studies that did include no-comparison groups have not found consistent and statistically significantly greater benefits for upward comparisons vs no-comparison controls, and the evidence for downward comparison is also mixed. The review notes that in most of the experiments, patients learn very little about the comparison patient beyond their relative standing with the patient. Consequently, patients may not perceive them to be appropriate proxies to assess their success in the future. The proxy model suggests that the remedy would be to present higher functioning proxies who share underlying attributes (age, socioeconomic status, life circumstances) with the patients. This kind of research has the potential to inform medical professionals about the kinds of comparison targets and instructions that would be most beneficial for psychoeducational materials (e.g., videos) in medical rehabilitation (see also Kulik and Mahler, 1987).

Social Inequality, Invidious Comparisons, and Health

A provocative finding in research on social determinants of health is what is referred to as the 'socioeconomic gradient' (Marmot, 2004; Wilkinson and Pickett, 2010). Individuals who rank higher in the social hierarchy enjoy better health than those who are below. Of course, poor nutrition, crowding, inadequate medical care, etc., no doubt, play a role. However, the association with health occurs at every level of the hierarchy, not simply below the poverty threshold. Marmot et al. (1991) found that individuals at the highest level of the British civil service had better health than those just below (all levels were well above the poverty line). Wilkinson and Pickett (2010) reported that differences in average income across countries had little effect on health, but where the person falls in the pecking order of their peers does have an effect on health. These researchers have proposed that invidious social

comparisons are the culprit, producing chronic stress among those lower on the social ladder, which may in turn increase the risk of psychological and physical illness.

This is a continuing area of research by health psychologists and epidemiologists as not all of the evidence is consistent, and political economists are looking for other explanations. Whereas some researchers maintain that relative standing influences health when one looks at aggregate-level studies (population or community levels), other researchers argue that only individual-level studies can differentiate between relative and absolute income effects on health (Wagstaff and van Doorslaer, 2000). The individual-level research has not shown definitive evidence implicating relative income. Our previous description of advances in basic theory and research also suggests that caution may be appropriate. The social gradient hypothesis assumes that upward comparisons are universally aversive, but as we have noted certain conditions facilitate upward assimilation. Some members of a population may convert a potentially invidious upward comparison into an inspiration. Income inequality also leads to lower happiness (Oishi et al., 2011). Between 1972 and 2008, Americans were, on average, happier in those years of lesser income inequality than in those years of greater inequality. This was true only of lower income people and was due to the feeling of unfairness and lack of trust rather than to household income itself. This means that the subtleties revealed by recent social comparison theory and research may have important societal consequences for a world in which income inequality is increasing.

Social Competence During Adolescence Across Cultures

Grace Iarocci and Emily Gardiner, Simon Fraser University, Burnaby, BC, Canada

Abstract

In this article, we consider what it means to be socially competent within the unique contexts that characterize adolescence. This critical period constitutes an especially salient time for examining social competence, as rapidly maturing developmental capacities have significant implications in terms of adolescents' rapidly emerging new social-cognitive resources, changing social goals, and shifting social focus. We discuss the key developmental milestones of adolescence, and illustrate the transactional nature of the social competence construct. Finally, we consider how socially competent processes and outcomes in adolescence may vary cross-culturally.

Developmental scientists have increasingly acknowledged the important role of social competence in children's everyday lives. Social competence has been studied from different levels of analysis, including at the level of cognition (e.g., perspective-taking), overt behaviors/skills (e.g., use of eye contact), and outcomes (e.g., social status, peer acceptance). However, social competence cannot be reduced to any single index or ability; the active and skillful coordination of multiple lower order as well as contextual processes are necessary in order to adequately meet the social demands of a particular situation (Iarocci et al., 2007).

Social competence is both a developmental phenomenon that can be measured over the course of a child's development (ontogenesis), as well as a characteristic of a particular social encounter where the time scale is in the order of seconds and minutes (microgenesis). Thus, continuities and discontinuities in its development are expected, as children are better able to coordinate abilities and take advantage of resources with increasing age, but may be less competent at certain developmental stages or in specific social contexts.

We must also consider that what constitutes socially competent behavior changes throughout development. Whereas in infancy social competency may be defined in terms of the quality of the parent–child relationship, the social world becomes significantly more complex in adolescence, and social interactions begin to require proficiency in a range of sophisticated social repertoires and skills (e.g., appreciation of social context/subtle social nuances, initiating and maintaining conversations, offering emotional support to others).

Adolescence is an especially salient developmental period for examining social competence. The transition to adolescence is marked by a rapid convergence of significant neurobiological, cognitive, emotional, and social transformation. It is recognized as the second major 'window' of development and change, next only in significance to early childhood. For example, significant advances in cognition, in particular metacognition and representational capacity, as well as competence in abstract thinking and complex problem solving, help youth to develop a differentiated and psychologically rich understanding of their social world. Relevant social interactions, such as those with parents, enhance the continued development of complex social understanding, and foster critical social competencies including empathy and self-understanding. However, entering this new social-psychological phase is accompanied by a change in social focus, as the amount of time spent with parents precipitously drops, while time spent with peers increases. During this transition, the parent–child relationship requires renegotiation as children strive toward autonomy and parents must find new ways of relating to, and being supportive of, their children.

Paradoxically, adolescence is both a time in which greater focus is directed inward toward self-reflection, as well as outward toward consideration of others' perspectives. These advancing reflective processes serve youth well with regard to self-identity formation, a key developmental task during this period, as they begin to consider how they are similar, yet also unique from their peers. During this time, the self is simultaneously differentiated from others and viewed in relation to others. A person's identity is shaped by social experiences (Martin et al., 2008) and therefore depends on the youth's ability to relate to others. Within the peer context, intergroup processes take on added significance as youth work to establish their own identity and status within the group. The steadily increasing centrality of peer and romantic relationships heighten the social challenges for adolescents. Those youth who successfully face these challenges improve their social competence whereas those who are unsuccessful may further diminish both their social status and social competencies (Monahan and Steinberg, 2011).

Social Competence in Adolescence

Social competence is conceptualized as incorporating characteristics of individuals and their environments, whereby these two sources of influence are transactional. Within this framework, social competence involves the active and skillful coordination of multiple processes and resources available to the child. Such processes include basic sensory/perceptual and cognitive abilities (i.e., attention, memory, motivation) fundamental to the development of higher-order social-cognitive processes. For example, sharing attention, understanding that others' thoughts and feelings differ from one's own, and expressing emotions and recognizing them in others, are only a few of the sophisticated social abilities involved in social competence. Furthermore, socially competent behavior also requires that a child coordinate these basic social capacities with available contextual resources

(e.g., opportunities for peer interactions). This higher-order coordination is a critical component of social competence because it permits children to appropriately match their social goals with the demands of the social context. Accordingly, social competence entails the development of strategic processes (i.e., techniques) that allow one to evaluate which resources are best given the demands of a particular task in a particular context. Social learning, through mediation and scaffolding, likely influence the development of these strategies or 'techniques,' as well as surrounding systemic factors. For example, the practices of parents and other relevant social mediators (e.g., teachers) play a significant role in shaping how social strategies are implemented in socially appropriate ways.

Various sociocultural systems influence the development of social competence through both proximal (direct) and distal (indirect) effects (Bronfenbrenner, 2000; Cicchetti and Toth, 1997). Direct influences include the youth's interactions with significant persons or events in their lives (e.g., parenting customs, sibling and peer relations, and teaching practices). Indirect influences are thought to emanate from macrosystems, or global-political contexts; mesosystems, which encompass the patterns, beliefs, and values of the culture in which the child exists; and exosystems, which comprise the various formal and informal social structures in the adolescent's environment, including the neighborhood, schools, and local government policies on education and health (Bronfenbrenner, 2000; Cicchetti and Toth, 1997). Within these systems, risk and protective factors are present throughout the course of development and may operate through distal and/or proximal processes to support or hinder the development of social competence.

With this conceptual framework in mind, we now focus on key developmental tasks (i.e., renegotiating parent–child relationships, developing friendships and intimate relationships, and self and cultural identity achievement) of adolescence that illustrate the transactional nature of social competence. The ways in which these major milestones are achieved both influence the future course of social competence development and are shaped by the adolescent's existing social competencies.

The Parent–Child Relationship

The parent–child interactions provide the primary social learning context from infancy. A variety of social-cognitive and socio-emotional processes, such as emotion regulation and recognition, referencing, gaze following, gesturing, and communication, are first evident in parent–child interactions. For example, between the second and third month of life there are significant developments in parent–infant behavioral synchrony, turn taking, and reciprocity, all of which are precursors to a healthy attachment. In typically developing children between the ages of 3 and 6 years, however, there is a marked decrease in time spent in direct contact with caregivers and a concurrent increase in time spent with peers. As such, peer relationships play an increasingly prominent role in a child's social development during the school years. This trend continues throughout middle childhood as increased availability of social opportunities is coupled with increased social interest, social-cognitive maturation, and independence. Despite these contextual changes, parenting behaviors, specifically those related to supporting children's changing developmental needs, continue to impact the child's burgeoning competence. While there are key parenting behaviors that support growth in social skill acquisition (i.e., warmth, sensitivity, and responsiveness), there are also those that interfere with, or hinder these developmental processes (i.e., parental negativity and overreactivity).

There is generally strong continuity of social competence during earlier developmental periods (from early childhood to middle childhood), yet studies of continuity from childhood to adolescence have yielded inconsistent findings (Obradović et al., 2006). Longitudinal studies have shown that although attachment classification in infancy does not predict attachment beyond childhood, functioning during childhood is significantly related to functioning in adolescence, which predicts future functioning in young adulthood (Simpson et al., 2007). Secure infants who are more socially competent in middle childhood have more secure friendships at age 16, and these individuals demonstrate greater emotional expression in their romantic relationships as young adults. Those who begin as secure are much more likely to experience high-quality relationships across development. Early attachment experiences are foundational and influence one's ability to form intimate and stable bonds over time. The parent–child attachment provides a framework within which the child forms expectations about the predictability of relationships. Those youth who have a secure attachment with their parents are likely to view peer interactions and relationships as similarly predictable and safe, providing a secure context for social exploration. Similarly, these early experiences influence later representations of romantic relationships, suggesting continuities between experiences with primary caregivers and the quality of later attachments (Roisman et al., 2009). Thus, although parents play a less prominent role during the adolescent period due to the changing demands of peer-dominated social interactions, an established secure base of parent–child attachment allows adolescents to form their own secure attachments with friends and romantic partners. Parents continue to be a significant influence in the development of social competence, but the relation between parent–child attachment and social competence is modest. For instance, accounts that include other mediational child variables, such as empathy, efficacy beliefs, emotional regulation, and social information processing, as well as community variables, such as neighborhood context, school factors, extracurricular activities, and religious involvement, may better explain the link between parent–child attachment and social competence.

Friendships and Intimate Relationships

During adolescence, peer relationships typically assume increased significance. The relationships that emerge during this time, such as close friendships and romantic relationships, tend to be less based on shared play activities and more on a higher degree of intimacy and self-disclosure (i.e., sharing of personal thoughts and feelings), greater mutuality, and increased reciprocity. During this period, a key behavioral expression of social competence includes the successful development and maintenance of more intimate peer relationships. This period likely involves both an emergence of new skills (e.g., social problem-solving and abstract reasoning), as well as

further developments in existing social-cognitive processes, such as perspective-taking (theory of mind), emotion processing, and pragmatic language abilities. Whereas gains in social competence enable individuals to better contend with social developmental tasks, the successful negotiation of these tasks, in turn, creates further opportunities for continued social learning and growth. For instance, close friendships with more competent peers provide adolescents with valuable social learning opportunities to refine and practice more sophisticated skills, and to receive important social feedback.

Self and Cultural Identity Achievement

Although the process of identity development may appear to be a solitary endeavor that occurs within the individual adolescent, the social-constructionist perspective on identity is that a self only exists in relationship to other selves (Martin et al., 2008). Related to this notion is that the choices adolescents have are typically constrained by their social situation, and similarly, their decisions are made within the context of societal demands. There are several cognitive shifts in higher-order reasoning about the self and abstract and conceptual ways of perceiving the self and others' perspectives that facilitate the exploration of various options. Alongside these cognitive milestones are important changes in the social landscape including emerging peer groups, cliques, and cross-gender relationships. Within these peer contexts, adolescents learn a great deal about the self, social and group conformity and deviancy, social hierarchies, and ostracism. In addition, moving in and out of different peer contexts provides opportunities for experimentation with 'trying on' various identities. Being included and accepted is important in the formation of one's identity, and the identity experimentation that inclusion allows may have a particularly formative impact on the development of social competence. For example, lonely or socially isolated adolescents are more likely to turn to the Internet to experiment with their identity, and apparently benefit from the relative anonymity that this setting provides in learning how to relate to people.

Social and cultural expectations about adolescence also have a profound impact on self-identity development. Parental and cultural beliefs about the adolescent's autonomy, responsibility, and achievements provide a point of reference for the adolescent. However, experimentation with social rules and structures is common. Through active exploration of alternatives to mainstream social roles, adolescents solidify their identities and eventually firmly adopt or reject certain social and cultural norms. Identity achievement occurs when the adolescent has explored and committed to fundamental aspects of their identity. Supportive parents, schools, and communities that encourage exploration are thought to promote identity achievement. Identity achievement is associated with higher self-esteem, increased critical thinking, and advanced moral reasoning in adolescents.

Some aspects of adolescents' identities, such as commitments to occupational, religious, or ethnic identity, may occur later in development. For example, unlike most adolescents of the majority culture, minority adolescents must consider the degree to which their racial or cultural background will be part of their identity. Identification with a minority culture may result in racism, ostracism, and marginalization, and thus, some minority adolescents are undecided or reluctant to make a firm commitment to a particular ethnic identity. However, developmental and social changes conspire to resolve this crisis in most youth. Whereas in early adolescence minority teenagers may deny any interest in their racial or cultural background, by the latter part of this stage, as moral reasoning becomes more sophisticated and social awareness of the relations between the dominant and subcultures are raised, minority adolescents may be ready to explore their heritage. Positive social interactions with other members of the same culture, and attendance at religious services or cultural events, can increase the adolescents' knowledge and instill a sense of pride in their ethnic background. Achieving a positive ethnic identity has been found to be associated with better grades, higher self-esteem, better relations with family and friends, and reduced physical and relational peer aggression.

Cultural Variations in Social Competence

Social competence is particularly advantageous in modern society as the cultural context becomes increasingly diverse. For adolescents developing in a multicultural environment, being able to effectively navigate the social-cultural demands of multiple and diverse perspectives is likely to be integral to their healthy social adaptation and development. However, to fully understand the impact of social competence on development, we must consider the variations in social relationships, social contexts, and social goals and values across cultures.

Developmental research on social competence specifically, or development more broadly, raises the long-standing concern about the universality of psychological principles and findings. Within a universalist framework, researchers determine whether 'universals' found in commonly studied groups hold true in others. However, we must also consider the varying social resources, demands, goals, and values that are reflective of the diverse environments in which social competence develops. Cross-cultural researchers refer to this period as 'adolescences' (Larson and Wilson, 2004, p. 299) to communicate the greatly divergent trajectories that individuals navigate during this period. This latter perspective is known as a relativist framework. This perspective examines each culture for its uniqueness, and is not concerned with establishing cross-culture commonalities (Iarocci et al., 2009).

In examining how the study of cross-cultural continuity and diversity can be approached, it is first important to consider the question: What is culture? This, too, is a diversely defined and complex construct that exerts significant influence in terms of a society's values, expectations, practices, beliefs, and patterns of interaction. We adopt Larson and Wilson's (2004) comprehensive definition:

> Culture might best be understood as the frame of reference that people begin acquiring in infancy and that molds how they think about themselves and others. It is embedded in the language one learns, one's intimate relationships and daily activities, the religion one is taught, and other existential fundamentals, such as when, where, and how one experiences different emotions. Each culture contains its own indigenous psychology, which includes developmental tasks and precepts, as well as postulates what is 'true, beautiful, good, and normal'. (p. 303)

This explanation highlights the pervasive influence of the cultural environment, and demonstrates how its influence extends across socio-ecological levels over time to become integrated within everyday actions and interactions. Thus, one's behavior cannot be evaluated as competent or not without a deep understanding of the specific social influences within the culture. It is the overarching norms and mores present within a particular society that dictate what is considered appropriate. For example, social behaviors considered critical for successful interaction in individual-oriented Western nations, such as sustained and appropriately modulated eye contact during conversation, may actually be considered socially inappropriate in others, such as in socially oriented Asian countries.

Researchers often draw distinctions between collectivist and individualist cultures. However, we must acknowledge that these are merely labels used to refer to aggregated groups of individuals who are not homogeneous. Modern adaptation to urbanization and globalization has led to the coexistence of elements from both dimensions, at least to some extent. This review is not intended to be exhaustive, and as such, will not delve into this discussion in detail. Instead we aim to provide examples that will highlight how interrelated social components contribute to one's expression of socially competent capacities in diverse contexts.

Diversity in Relationships

Resources that are essential to the development of social competence emerge from the interactions that take place between children and their primary caregiver(s). In Western nations, child-rearing activities primarily fall to the nuclear family unit and positive social outcomes are associated with secure child–caregiver attachment. In cultures where child-rearing may rely on greater involvement from extended family or community members, such as Israeli kibbutzim, hunter-gatherer tribes in African cultures (e.g., Dogon of Mali, Efé of Congo, and Gusii of Kenya), and Aboriginal communities, it is important to consider the diversity in caregiving contexts and the potential implications for social competence. Interestingly, even in such distinct settings, the importance of a secure attachment with the primary caregiver(s) emerges as critical. For instance, infants raised in kibbutzim who are securely attached with their mother or father have been found to attain higher school achievement and demonstrate greater emotional maturity, as well as have higher self-perceived social acceptance and self-esteem in adolescence, all of which enable an individual to participate competently in social interaction (Sagi-Schwartz and Aviezer, 2005).

In Western societies, authoritative parenting has consistently been identified as the ideal style over authoritarian, indulgent, or neglectful parenting. Authoritative parent–adolescent interactions are characterized by high degrees of warmth, control, and autonomy granting, and are associated with positive adolescent outcomes including higher academic achievement, fewer mental health concerns, and stronger self-esteem (Steinberg, 2001), yet this is not universal. Authoritarian parenting, distinguished by high control and low warmth, has been associated with the same kinds of positive outcomes in American minority cultures, such as for African-American children and adolescents, as well as for adolescents in Asian societies, such as China, Japan, Vietnam, and South Korea. In comparison to Western parents, those who utilize nondemocratic approaches (i.e., parents' boundaries are nonnegotiable) may be designated as low in parental warmth. However, close attachments can still be characteristic of these relationships. It is likely the ways in which these high-control approaches are interpreted within the relevant cultural context (i.e., as indicative of interest and concern), as well as how they are representative of broader societal circumstances and values, that mediates these different developmental pathways. For example, authoritarian parenting may be protective in collectivist societies that place great importance on respect for authority and group cooperation. Authoritarian-like parent–child interactions, in which adolescents must submit to parental rules, may be more culturally appropriate in such environments as they prepare children to comply with the implicit group harmony-focused social demands of their society. These mechanisms may also have great practical relevance within North America where neighborhoods characterized by low socioeconomic status, high ethnic and racial diversity, and a high proportion of young people are associated with greater violence and delinquency. In circumstances such as these, parents may adopt high-control approaches in an effort to prevent their children from becoming engaged in risky activities.

Diversity in Social Contexts

Adolescence is a developmental period that involves confronting novel social challenges and demands. These may include navigating the complexities associated with more intimate peer and romantic relationships, as well as adopting greater responsibility in contributing to the family economy. Although the demands facing adolescents in Western and non-Western societies differ, this divergence is actually greatest when examining how imposed expectations vary across genders in diverse cultures. Male and female experiences during this stage can be so "dissimilar as to constitute separate adolescences" (Larson and Wilson, 2004, p. 319). For example, in areas of the Middle East, Latin America, Africa, Asia, and South Asia, entering adolescence is accompanied by a drastic transformation in roles. Males are granted increased autonomy and are encouraged to spend time with peers, whereas females experience restrictions on their independence, as unsanctioned relations with the opposite sex are considered highly inappropriate and may bring shame upon the family (Larson and Wilson, 2004; Lee et al., 2010). Moreover, females are often expected to fulfill caretaking roles by taking on greater domestic and childcare responsibilities. In contrast, males are encouraged to assert themselves, to express their ideas, and to make their own decisions. Although these latter behaviors may appear to be consistent with the goals of those within Western society, research conducted with adolescents in Taiwan identified that gender was a better predictor of autonomous thought than cultural value orientation (i.e., collectivistic or individualistic), demonstrating that these patterns may not be reflective of a West-East dichotomy, but of a stark division in how the two genders are viewed and socialized cross-culturally (Lee et al., 2010).

Social demands and expectations become particularly complicated as non-Western societies become introduced to

Western ideals and practices through urbanization, globalization, and increased access to information (i.e., greater use of the Internet and social media, and exposure to international broadcasting sources). This can result in value system adaptations in younger generations, coupled with the presentation of competing demands imposed by different groups (i.e., peers and family). For example, parents may assume that their adolescent daughters will embrace values from their culture of origin; however, the adolescent may perceive these values as outdated or incongruous with their 'idealized' culture. These conflicts are evident even in groups that have emigrated from non-Western societies to Western countries. For example, adolescent daughters whose parents immigrated to Canada from India, Pakistan, and Bangladesh seem to experience a mismatch between their traditional social cultural expectations and those of the Western setting in which they live. These youth were discouraged from intermingling with their Canadian peers, social interactions were highly supervised, and they reported that they were viewed as inferior in comparison to male peers (Talbani and Hasanali, 2000). Children of immigrants must navigate at least two, at times incompatible, cultures to both successfully meet the social demands of their same-aged native-born peer group as well as maintain ties to their cultural heritage.

Aboriginal groups worldwide may share a similar experience even though their histories involved persecution and colonization rather than emigration. In Canada, the term 'Aboriginal' refers to the country's original inhabitants prior to the European invasion. First Nations (the indigenous peoples of the Americas located within the boundaries of Canada, excluding the Arctic), Inuit (indigenous peoples located in the Arctic), and Métis (persons of mixed European-First Nations ancestry) are collectively referred to as Aboriginal peoples. These groups share a history of oppression and loss of culture that has had a deleterious impact on subsequent generations. Currently, youth strive to participate and succeed in the majority culture, which, in some cases, comes at a significant cost to their own personal as well as the collective well-being. The risk and protective factors associated with identification with ancestral identity have begun to be studied among Aboriginal youth. There is growing evidence that identification with one's cultural heritage is particularly protective for these youth with regard to peer relations and educational and social outcomes.

Diversity in Social Goals and Values

In Western societies, adolescence is typically conceptualized as a developmental phase in which central milestones include asserting greater independence, forming a unique identity that distinguishes adolescents among family members, and shifting social focus to the development and maintenance of stronger peer relationships. However, social goals in adolescence vary across cultures. For example, in non-Western countries, including India and Asia, as well as across Arab societies (e.g., Algeria, Saudi Arabia, Lebanon, Palestine, Egypt, and Jordan), the social goals of adolescence are not peer focused but remain family centered. These adolescents often remain more connected with their family members than their North American counterparts do, viewing their parents as companions, spending more time in their company than with their peers, and confiding with their parents about personal matters. The parent–adolescent relationship renegotiation characteristic of the West is also not a central developmental task in such contexts, as these relationships remain hierarchically organized, with adolescents expecting to defer to parents' authority. In such societies, family interdependence, as opposed to independence, is the goal (Dwairy et al., 2006).

Interdependence is also a central concept around which adolescents in collectivist cultures base their identities. In this setting, the self is defined as a 'we-self,' as opposed to a 'me-self,' and reflects the individual's ability to conform to the values and goals of the broader society. It is less tied to how one is unique or what can be achieved independently. In interdependent contexts, socially desirable, and therefore also socially competent, individual characteristics are those that facilitate harmonious group functioning, such as shyness, cooperation, and vigilance. In stark contrast, these qualities may be pathologized in North America, with numerous studies documenting the socially maladaptive outcomes associated with introversion. In the latter context, adolescents are expected to be assertive and independent, and individuals who effectively communicate such qualities enjoy greater social opportunities. Thus, socially competent behavior must be evaluated with an understanding of the social goals and values of a particular society.

Adolescence is the ideal frame of time to capture the multidimensional and transactional landscape of social competence. The unprecedented changes in social abilities and opportunities during this developmental period shape, and are shaped by, social competence. However, there are important variations in social relationships, social contexts, and social goals and values across cultures that must be considered to fully grasp the impact of social competence on development.

Social Constructionism

Abstract

Social constructionism is a term used to refer to a number of related theoretical approaches that challenge the underlying assumptions and research practices of mainstream psychology. Its insistence upon the historical and cultural specificity of all knowledge means that it constitutes a radical critique of the discipline. Its focus on the importance of language in the construction of people and events has led to the adoption of several varieties of discourse analysis as its research methods of choice.

Introduction: the Origins of Social Constructionism

Social constructionism is a relatively new term in the social sciences, especially psychology. But the ideas and practices that have cohered around this term in recent decades have a longer history in disciplines such as sociology, philosophy, and linguistics. The key tenet of social constructionism is that our knowledge of the world, including our understanding of human beings, is a product of human thought rather than grounded in an observable, external reality. Although very different in other respects, the philosophers Kant, Nietzsche, and Marx all took this view; important concepts in the sociology of knowledge developed during the twentieth century, such as ideology and false consciousness, reflect this key tenet, focusing on how sociocultural forces construct knowledge and on the kind of knowledge they construct.

But an important contributor to social constructionist thinking has been the microsociological approach of Symbolic Interactionism, cogently laid out in the now classic book *The Social Construction of Reality* (Berger and Luckmann, 1966). In the early twentieth century, George Mead, at the University of Chicago, developed this approach from the earlier work of Herbert Blumer and later published his ideas in *Mind, Self and Society* (1934). Mead had studied at Leipzig University under Wilhelm Wundt, who is widely acknowledged as the founder of experimental psychology. However, Wundt is less well known for his belief in the importance of sociocultural factors, such as myth, folk customs, and religion, in understanding human behavior and experience. Mead took up these ideas in his development of Symbolic Interactionism, which argues that people construct and negotiate identities for themselves and others through their everyday social interactions with each other. Language, as a system of socially shared symbolic meanings, is central to this constructive process. Ironically, John Watson, later to become one of the key expounders of behaviorist psychology, studied under Mead as a postgraduate student. Watson's rejection of the concept of 'mind' and his focus on decontextualized behavior was antithetical to Mead's own position, and their relationship deteriorated. When a new psychology department was set up at Chicago, the split between Watson and Mead was mirrored in the subsequent disciplinary separation of psychology from sociology. This division persists today and consequently few undergraduate psychology students have the opportunity to learn of approaches such as symbolic interactionism and the mainstream discipline continues to operate within a socially decontextualized model of human behavior and experience. In addition to these North American influences, social constructionism has also drawn on the ideas of more recent European thinkers. The work of the historian and philosopher Michel Foucault has been highly influential, as has that of Ferdinand de Saussure in structural linguistics, of the philosopher Jacques Derrida's work on 'deconstruction' and of the psychodynamic theorist Jacques Lacan. The ideas of these writers have been extensively drawn upon in developing social constructionist thinking around the role of language in the construction of human social phenomena.

The influx of some of these ideas into psychology was encouraged in the later half of the twentieth century by the increasing dissatisfaction with and unease about their discipline of a number of social psychologists. What came to be known as the 'crisis in social psychology' (e.g., Harré and Secord, 1972; Armistead, 1974) centered on mounting worries about the way that social psychology's agenda was driven by the needs and motivations of powerful factions (government, the military, and commerce); its theories and research findings often seemed to bring further oppression to relatively powerless and marginalized groups (women, ethnic minorities, working class people, and those of non-normative sexual orientation) and this operated partly through the study of human phenomena in socially decontextualized laboratory environments, since experiments ignored the real-world contexts which, it was argued, give human conduct its meaning. There was a move to attend to this social context, as well as to explore human phenomena from the perspective of psychology's 'subjects' themselves rather than to overwrite this with the perspective and voice of the relatively powerful researcher. These concerns encouraged social psychologists to embrace the ideas already flourishing in neighboring disciplines, including microsociology, and also fed into the increasing call to recognize qualitative research methods as legitimate and fruitful for the discipline of psychology.

Epistemology

Social constructionism poses a radical challenge to the epistemological position assumed by mainstream psychology. Psychology has followed the natural sciences in its vision of scientific endeavor, and this vision of science was born in the Enlightenment historical period.

The Enlightenment was characterized by the search for objective truth through reason and rationality. Science was to challenge the dogma and superstition of the medieval period when knowledge was handed down by religious leaders and was to be unquestioningly accepted. The Enlightenment challenged the church's monopoly on truth and proposed that individual people (increasing numbers of whom, with the invention of the printing press, could read the scriptures and scientific publications for themselves) should be responsible for developing their own knowledge, and discover the truth for themselves; individuals should draw their own conclusions about the nature of the world, and how to live in it, based on objective, scientific evidence. This vision of scientific endeavor, focusing on the systematic observation and recording of phenomena, became known as positivism and is closely allied with realism (sometimes referred to as naive realism), the idea that through our observations of the world, objective reality will be revealed to us. The philosopher Auguste Compte (1798–1857) was a central contributor to the idea that science could discover 'laws' of human nature just as it was doing for the natural world. It is important to appreciate the role of positivist thinking in challenging the power of religious dogma and superstition. Nevertheless, the capacity of science to capture the true nature of the world through empirical investigation is what social constructionism, in its turn, now challenges.

Social constructionism problematizes the claim that what we call knowledge, our current understandings of the nature of the world and its phenomena, is derived from objective, unbiased observation of events; that what exists is what we perceive to exist. Neither does it argue that the problem lies in systematic biases operating within scientific method. The concept of bias in turn rests upon the concepts of truth and accuracy, both of which social constructionism also challenges. The solution is not, therefore, to improve scientific method in order to reduce its biases; truth and accuracy are rejected as meaningful conceptual tools because social constructionism's epistemological position is one of relativism. Sometimes referred to as perspectivism, this position argues that there can never be one objective, final and 'true' account of phenomena; instead what exists are multiple perspectives, potentially as many different versions of events and things as there are people in the world. What we call knowledge, which we regard as facts, can therefore not be compared to an accurate standard to assess its truthfulness; instead, different ways of understanding the world coexist in parallel and none of them can be said to be the truth. Rather than pursuing a search for objective truth and the nature of the real world, social constructionism recommends that we take a critical and skeptical attitude toward our taken-for-granted ways of understanding the world.

Time and Place: Knowledge in Context

One of the earliest and most influential social constructionist publications within psychology came from the North American psychologist Kenneth Gergen in 1973. His paper *Social Psychology as History* argues that all knowledge, including psychological knowledge, is the product of a particular historical period and of a particular cultural location. He reframes social psychology as a historical, rather than scientific, project. The constructionist case is that all human psychological and social phenomena arise out of social life, from the interactions between people. These interactions in turns are given structure and content by the culture in which we live, by our society's economic conditions, and by the power relations in which we are embedded. But these social conditions are subject to constant flux. From time to time, and from location to location, the conditions within which people construct themselves and each other differ and are transformed. It follows, therefore, that there can never be definitive answers to questions about the nature of human and social phenomena. Instead, Gergen recommends that we ask how and why certain constructions come into being. This of course includes the constructions that we call 'theories,' and so the very projects of psychology and social psychology themselves become questions about history and culture. To properly understand the evolution of present-day psychology and social life, we therefore must extend our enquiries beyond the individual into social, political, and economic realms. Social constructionism also challenges the very categories of things and people that characterize our (current, local) thinking and language. We cannot imagine dispensing with categories and dichotomies such as urban/rural, male/female, individual/society, or mental/physical, but social constructionism proposes that these are human constructions rather than objective descriptions of the world and at least some of them would not have made sense to people living in earlier historical times.

Such a view disrupts the notion of scientific progress, the idea that through science we are advancing toward a more and more accurate understanding of the physical and psychological world. Our contemporary conceptions of, say, children, illness, or sexuality are certainly different to what they were 100 or 200 years ago, and may differ radically from ways of thinking in non-western, industrialized cultures. But social constructionism cautions against making the assumption that our current, local ways of thinking are better because they represent a more accurate or truthful account. Such thinking, it is argued, is responsible for the imposition of our own ways of thinking upon other cultures and nations; psychology has been imperialist in its view of other cultures and has colonized them, replacing their indigenous conceptions of human life with western-grown ideas. The model of human beings intrinsic to contemporary psychology is a particularly individualistic one, a model which celebrates and privileges the unique, self-contained person. Social constructionists argue that this individualism became part of the discipline of psychology as it developed and flourished in North America, where the individual is arguably especially valorized (Farr, 1996).

Challenging Psychology's Model of the Person

Antiessentialism

The vision of the person lying at the heart of mainstream psychology is the self-contained individual, an autonomous and agentic person that preexists society and social life. This vision is expressed in Floyd H. Allport's (1924: 12) definition of social psychology: "The science which studies the behavior of the individual in so far as his [sic] behavior stimulates other

individuals, or is itself a reaction to this behavior." This pre-existing individual has a discoverable nature, and the agenda of psychology is its discovery. The content of this individual is described by the various and competing psychological theories that have been developed over the last 100 years or so: personality traits and intelligence, unconscious motivations and drives, learned behaviors and habits, attitudes, and beliefs. All these constructs are similar; however, it that they are thought of as properties of the person, whether inherent or acquired. Social constructionism regards all such concepts as constructions, and like any other constructions, they have arisen in the course of social life in particular sociocultural conditions. This position is referred to as antiessentialism, and stands as a critique of the notion of psychological essences, structures, or qualities that exist at an intrapsychic level as properties of individuals. Social constructionism also therefore challenges the determinism of psychology, its assumption of causality. This is the view that psychological and social phenomena are caused and explained by events or structures either in the individual's environment (such as upbringing or traumatic events) or internal to them (such as personality traits or the actions of hormones).

Rejecting Reductionism

The essentialism and determinism of mainstream psychology are also expressed in its reductionist thinking. Reductionism is the attempt to explain complex events in terms of simpler, lower level ones. Levels of explanation are typically arranged from the biological (genetic material, brain activity, hormonal activity, etc.) through the psychological (behavior and experience) to the social/societal (social structures and social phenomena). In this way, complex social phenomena, such as poverty, crime, and alcoholism, are reduced to and explained by events or structures at the psychological level (such as intelligence and personality) which are in turn reduced to and explained at the biological level, often genetic inheritance or brain structures.

This reductionism is not confined to the discipline of psychology but is increasingly evident in popular understandings of a great range of social and psychological phenomena. The burgeoning discipline of neuroscience has taken centre-stage in popular understandings of human experience, so that we are invited to understand psychological events as caused by events happening at a neurological level. Gergen (2010) is critical of this, arguing that it leads to fatalistic thinking; if behavior is seen as caused by neurological events, over which we have no control, personal agency is an illusion and we may simply blame our wayward brains for the acts we commit. Gergen offers a constructionist challenge to such thinking, arguing that the psychological behaviors, events, or properties that neuroscience purports to explain, for example, aggression are complex, changeable social constructions subject to local interpretations. It is therefore not possible to identify causes of such phenomena, whether neurological or not.

The Centrality of Social Interaction and Discourse

Social constructionism turns on its head the relationship between the individual and society implicit in Allport's definition of social psychology; what we recognize as individual persons cannot exist without a preexistent social network. Human beings are born into a world of social relations, language, norms, and customs and it is this social world that constructs them as recognizable persons who are capable of meaningful conduct. In this sense, it would be legitimate to say that all psychology is social psychology; there is no part of an individual's functioning that does not have its origins in social life in one way or another. As in symbolic interactionism, the very contents of our thoughts, what we call our attitudes and beliefs, our sense of self, all these things arise out of interaction with others. The constructionist John Shotter (1995) writes about 'joint action' as a way of conceptualizing the social origins of thought and behavior. Kenneth Gergen (1999), drawing on the work of Lev Vygotsky and the philosophy of Mikhail Bakhtin, argues for a relational, dialogical approach to the self. He writes of the interconnectedness between people; we are locations in a network of myriad 'voices,' past and present. Gergen has since developed these ideas into a political vision of the self, deconstructing and challenging the self/other dichotomy upon which much conflict arguably rests. The constructive work that produces us as persons takes place in social interaction of all kinds, and language as a key constituent of social interaction is therefore of great importance. Discourse is at the heart of social constructionism, and this term has been used in different ways by two approaches that have developed within social constructionism, which can broadly be called the 'macro' and the 'micro' approach (Burr, 2003).

The macro approach draws heavily on the work of Michel Foucault, who argued that discourses are widely prevalent ways of talking about or otherwise representing (such as in images, written materials, films and even buildings and other physical spaces) people or things and these discourses function to construct and maintain our understanding of those people and things in social life. Through his method of the 'archaeology of knowledge,' he traces the discourses historically producing contemporary constructions of phenomena such as mental illness (Foucault, 1964) and sexuality (Foucault, 1976). Our talk about such things is reframed as manifestations of these discourses, almost as if they were speaking through us. In its most extreme form, this view renders people the hapless carriers of discourses who are also constructed by them in a rather deterministic fashion; our identities become multiple and changeable, distributed across the discourses that construct us. However, taking this approach brings to fore the issue of power, something which psychology has arguably neglected. Prevailing discourses are said to be constructed in the interests of the relatively powerful (in general, white, middle-class men), it is relatively powerful in society that has the greatest opportunity to disseminate such discourses and it is their status (for example, as members of the medical profession, the law, or the state) that authorizes and legitimates them. This approach is therefore able to offer an understanding of how psychology as a discipline has contributed to the oppression and marginalization of some people.

The micro approach is associated principally with work that came to be known as discursive psychology (e.g., Edwards and Potter, 1992). Discourse here is taken to refer to our everyday linguistic practices, particularly spoken interactions. The focus here is not on the constructive power of prevailing discourses, but on the constructive work that people do in interactions in

order to build accounts of themselves and events that are effective for them. The key ideas here were laid out in the now classic publication by Jonathan Potter and Margaret Wetherell (1987). Using their own interview research data, which examined racism in New Zealand, they reject the mainstream social psychological concept of attitudes as an explanatory tool. Focusing on the variability within participants' accounts, they propose instead that interactants' talk is occasioned by the moment-to-moment needs of each party in the conversation; these needs might include, for example, justifying one's actions, attributing blame to another for the outcome of events or creating a good impression.

One danger here is that these two approaches threaten to recreate the mainstream division between the individual and society, with the macro approach being socially deterministic and the micro approach seemingly reinstating the agentic individual. However, the macro and micro approaches are not in themselves incompatible and some have been keen to explore how they might be synthesized. One such attempt is in the concept of 'positioning,' put forward by the philosopher of science Rom Harré (Harré and Van Langenhove, 1999). Here, persons are simultaneously positioned by discourses (the macro approach) and draw on these to position themselves and others within specific interactions (the micro approach).

Research

Social constructionism challenges mainstream psychology's approach to research, critiquing the laboratory experiment, in particular, for its socially decontextualized approach to understanding the person. As social constructionism has developed, various theoretical and methodological preferences have emerged within it, and there are now a number of approaches to the analysis of research data that can broadly be called 'discourse analysis'. The macro and micro approaches outlined above are characterized by their own research questions and associated methodologies, although the latter are predominantly qualitative. Those who wish to focus on the constitutive force of discourse and analyze the power relations implicated in subject positions have favored a Foucauldian approach, and Fairclough's (1995) method of Critical Discourse Analysis has gained popularity for such purposes. This kind of approach has been enthusiastically taken up by some feminists and others who wish to conduct research which exposes the oppressive use of discourse and address the marginalization of relatively powerless people.

Research focusing at the more micro level of social interaction has cohered around the practice of what has come to be known as 'discursive psychology'. The research focus here is everyday language as it is used by ordinary people in the course of social interaction. Drawing on the sociological subdiscipline of ethnomethodology, its focus is upon identifying the processes by which ordinary people construct and build accounts of themselves and events. Early work from this orientation used the conceptual tool of the 'interpretative repertoire,' with research aiming to identify the repertoires used by people when accounting for events, often in research or other interviews. Later developments in discursive psychology have led to a greater focus on identifying the use of a range of rhetorical devices (such as justifications and blamings, three-part lists, and extreme-case formulations) used by interactants to construct their accounts in naturally occurring conversations. To this end, discursive psychologists have typically adopted a version of Conversation Analysis as their preferred research method.

Issues and Debates

Realism vs Relativism

The relativist epistemology that appears to be a key feature of social constructionist thinking is regarded by many as deeply problematic has, in the past, been hotly debated (see the special edition of *Theory and Psychology*, 11 (3), published in 2001). Relativism appears to undercut political efforts to challenge oppressive practices and to take a moral stance since it is impossible to demonstrate the 'truth' of one version of events, the superiority of a particular moral code, over any other; one view is as valid as any other, and 'anything goes'. The difficulty appears to be the impossibility of specifying a reality that exists beyond language. This has led to the development of 'critical realism'. Originating with the philosopher Roy Bhaskar, critical realism argues that social systems are real; they are constructed by people and have real causes and constraints that are external to individuals. Oppressive systems and structures may therefore be critiqued as they have an objective existence beyond discourse. Such a position has been important for those researchers who are keen to analyze power relations, especially in relation to marginalized experiences or groups. Indeed, discursive psychology has been criticized for its failure to contextualize social interaction within broader power structures, while discursive psychologists argue that a Foucauldian approach neglects actual everyday language as used by real people.

However, discursive psychologists claim that social constructionism's relativism has been misunderstood. Edwards et al. (1995) argue that social constructionism does not deny the existence of a real, material reality but that this reality is always brought into social being through language and is transformed in this process. Others disagree that relativism is in itself morally problematic. For example, Gergen (2001) believes that the strength of relativism is that it constantly demands argument and debate. Moral and political positions must be argued for and discussed, and this process is the best way of guarding against any one version of truth becoming legitimated and generally imposed. The heat in this debate now appears to have dissipated, with writers generally adopting and justifying one or other of the above positions or their variants.

Identity and Subjectivity: the Relationship between the Individual and the Social

Early enthusiasm for the Foucauldian approach to discourse within social psychology subsequently raised concerns about the loss of anything we might recognize as the psychological content of the person, and about the danger of replacing the determinism of mainstream psychology with a determinism that is simply social/discursive instead. And despite discursive psychology's focus on the individual use of language in interaction, which focuses on the agentic use of language by skilled social actors, the interior life of the person was effectively

'bracketed off,' much as it had earlier been for behaviorism. Another concern was the absence of any embodied presence of the person within social constructionist thinking. If social constructionists were to understand how people construct meaningful identities for themselves and are able to challenge and resist dominant discourses, the person as a psychological being needed to be reinstated, but in a radically different form to the self-contained, liberal-humanist conception of the individual in the mainstream discipline. An early attempt to do this is represented in the edited collection *Changing the Subject* (Henriques et al., 1984), with contributors drawing on (psychoanalytic) Lacanian and object-relations theory to make good the absence of psychological processes from the socially constructed person. Within social constructionist writing, psychology's key traditional concept of personality became replaced by those of identity and subjectivity, to signal the strong social and discursive origins and situatedness of personhood. However, reinstating interior, psychological life as a valid focus of enquiry was not enthusiastically taken up by social constructionists across the board. Now sensitized to the political implications of psychology's historical individualism, many feared backslide into such ideas and were deeply suspicious of any reference to the self.

Nevertheless, psychologists working within a social constructionist framework have made continued efforts to theorize and remodel psychological subjectivity. The concept of 'subject positions' within discourse has become particularly widely used. Davies and Harré (1990) propose that when people take up positions within discourses (for example, as women or men within discourses of gender, or as gay or straight within discourses of sexuality), these positions inevitably provide us with a particular perspective on the world, with affordances for what can meaningfully be said and done from that subject position. The term 'subjectivity,' Frosh (2003) argues, signifies both being subject to (discourse) and being a (psychological, agentic) subject who acts. This concept has become a key focus of a relatively new approach which has emerged over the last 10–15 years, referred to as psychosocial studies. Following a critical agenda, much work within psychosocial studies draws heavily on psychoanalytic theory and is concerned to address the problematic dichotomy of individual/society in a new understanding of subjectivity. Some see the aim of psychosocial studies as transcending this dichotomy such that its poles "are instead thought of together, as intimately connected or possibly even the same thing" (Frosh, 2003), echoing earlier attempts to provide an alternative to the agency/structure debate within sociology (e.g., Giddens, 1979). However, others (e.g., Jefferson, 2008) argue that the 'psychic' is lost in such a conceptualization. In this context, the terms subjectivity and identity are themselves contentious within psychosocial studies. Originally intended as a new way of conceptualizing the relationship between the psychic and the social (Venn, 2006), some (e.g., Wetherell, 2008) are concerned that the psychic realm, under the label of subjectivity, once more becomes one pole of the old individual-social dichotomy with identity occupying the social pole, representing a backslide into dualistic thinking. Wetherell argues that what we regard as features of both social identity and subjectivity are themselves socially constructed, and recommends 'psycho-discursive practices' as a more fitting conceptual tool.

Social Constructionism in Psychology

In the foreward to their (1998) reissue of *Changing the Subject*, the authors comment that since the time of the first edition, there had been little take-up of social constructionism's challenging ideas by the mainstream discipline. This situation seems to have continued, at least outside of mainland Europe, with academics researching and writing principally within one realm or the other. New academic journals have been developed which welcome social constructionist and discursive work, while many preexisting mainstream journals continue to favor work carried out within a traditional, positivist framework. Social constructionist work within psychology can now be said to be broadly subsumed under the umbrella term of 'critical psychology' (Fox and Prilleltensky, 1997), but there has been relatively little productive dialogue between mainstream psychology and social constructionism/critical psychology, the two paradigms, and their agendas, continuing to lead more or less parallel, self-contained lives. Frosh (2003) notes that the more recently emerging field of psychosocial studies has in the main developed outside of academic psychology, and there has been little dialogue between these.

Social Constructivism

Wolfgang Detel, University of Frankfurt/Main, Frankfurt/Main, Germany

Abstract

The introduction of this article presents a sketch of the three main current versions of social constructivism (social epistemology, strong social constructivism, and social ontology) and of the historical background of social constructivism (Section Social Constructivism – Variants and Background). The following three sections outline these three approaches in some more detail and assess them briefly. Concerning social epistemology, veritistic and nonveritistic approaches to social epistemology are discussed (Sections Social Epistemology (Weak Social Constructivism), The Veritistic Approach to Social Epistemology, and Nonveritistic Approaches to Social Epistemology). Concerning strong social epistemology, views about ontology and the social are addressed (Sections Radical (Strong) Social Constructivism, Strong Social Constructivism and Ontology, and Strong Social Constructivism and the Social). And concerning social ontology, first a currently much debated specific example (social ontology in theories on international relations) and then the general approach to social ontology are characterized (Section Constructivism about the Social (Social Ontology), Constructivism and International Relations, and Nonveritistic Approaches to Social Epistemology).

Social Constructivism – Variants and Background

Facets of Social Constructivism

"Social construction is … an idea that has been cropping up all over the place … and is bitterly fought over in the … culture wars" (Hacking, 2000; VII). The core idea of social constructivism in its broadest sense is that some things are produced (and in this way constructed) by social actions, i.e., by actions that we carry out by interacting with other people. There are certainly many things that are socially constructed in this sense, for instance many artifacts, some emotions, and a number of novels. Social constructionists argue, though, that there are a lot of things that seem to depend, at first sight, exclusively on nature and natural laws such that they could not be changed by human actions but that, on closer examination, turn out to be socially constructed and thus alterable by humans. In these cases, social constructivism is taken by its proponents to be a liberating idea being critical of the status quo. It is in this more special version, not in its broadest sense, that the idea of social construction is bitterly fought over. Even in this special sense social constructivism comes in many different variants. It can be concerned with different kinds of things, notably with (1) beliefs, (2) facts or (3) social relations. And it can imply differently strong commitments as to the social construction of X, in particular that (a) X is not inevitable (against first sight), (b) that X is, in addition to (a), a bad thing, and (c) that X is, in addition to (a) and (b), a thing we would be better of if it were at least considerably be transformed, if not destroyed.

The most fundamental and interesting battles over social constructivism are debates about case (a), since if (a) is false, then (b) and (c) are irrelevant. At the same time, (a) does not imply (b), nor does (b) imply (c). Concerning beliefs, social constructivism is a view about the social nature of knowledge and science (sometimes labeled social epistemology or weak social constructivism). Concerning facts, social constructivism is an idealistic view about the social construction of scientific facts and sometimes even about empirical facts (sometimes labeled radical or strong (social) constructivism). Finally, concerning social relations, social constructivism is a view about the construction of the social realm (sometimes labeled social ontology). Social epistemology and radical constructivism take social relations and social actions as given, using them as explanantia. In contrast, social ontology takes social relations and social actions as explananda and is therefore, from a theoretical point of view, the most fundamental version of social constructivism. In this entry, the discussion of social constructivism will be restricted to case (a) concerning beliefs, facts, and social relations.

Historical Background of Social Constructivism

Historically, social constructivism is rooted in historical materialism developed by Marx. Historical materialism is best understood as a research program, roughly in the sense of the methodology of research programmes proposed by Lakatos, the core of historical materialism consisting of the claim that the economic base of a society determines its superstructure. This core is supposed to generate testable historical theories or hypotheses about what, in various societies, the base and the superstructure are, and about the specific ways in which they are interrelated. The strongest, but not the only possible, interpretation is that the superstructure is causally determined by the base. This approach was taken up by sociologies of science worked out during the twentieth century. Thus, for instance, Karl Mannheim wanted to show how humanities and theories of society are socially determined (Mannheim, 1936); and one of the leading American sociologists of science, Robert Merton, suggested that it is primarily the rise and success of science that is determined by social forces (Merton, 1973) (*see* Social Science, the Idea of).

Another important intellectual source of social constructivism is the historical turn of the twentieth century philosophy of science (Kuhn, 1962; Bachelard, 1934; Canguilhem, 1966;

Foucault, 1969; Hacking, 1990). This movement is vigorously opposed to scientific realism and rejects the claim, so crucial for the traditional philosophy of science, that there are universal rational scientific methods and rules such that the history of science can be rationally reconstructed as an continuous intellectual enterprise constantly improving our scientific knowledge by applying these methods. Instead, proponents of the movement see the history of science and scientific beliefs shattered by contingent breaks and dependent on normative attitudes and hidden nonscientific assumptions that an adequate philosophy of science must aspire to reveal.

A third theoretical background of social constructivism is the program of naturalizing epistemology initiated by Quine (Quine, 1969). The crucial idea of this program is that traditional epistemology centering around the question of the justification of claims to (scientific) knowledge should be replaced by a scientific study of causal processes of belief formation and information. In this way, epistemology is supposed to be transformed into a natural science.

In sum, there are three historical ideas that guide approaches to social constructivism, borrowed from a broadly Marxist sociology of science, from the historical turn of twentieth century philosophy of science, and from the program of naturalizing epistemology, namely that the development of scientific knowledge is (1) determined by social forces, (2) essentially contingent and independent of rational methods, and (3) should be analyzed in terms of causal processes of belief formation.

This is not to say that all versions of social constructivism are guided by all three ideas. On the contrary, there are veritistic approaches relying on the claim (1), but rejecting claims (2) and (3), and nonveritistic approaches entertaining all three claims (1)–(3).

Social Epistemology (Weak Social Constructivism)

Social epistemology rests on the methodological assumption that a sociological analysis of science and scientific knowledge can be empirically fruitful and epistemologically illuminating. This assumption has generated detailed empirical studies of scientific practices (for instance, of what is going on in laboratories on a day-to-day basis). However, there are two sorts of social epistemology: veritistic and nonveritistic social epistemology.

The Veritistic Approach to Social Epistemology

The veritistic approach to social epistemology seeks to identify, and to evaluate, social interactions, practices, and forces that influence – in a positive or negative way – the pursuit of the fundamental aim of traditional science (spelled out in classical philosophy of science), i.e., the production of true justified beliefs (Goldman, 1978, 1987, 1999). On this view, science and education place a high value on having true beliefs rather than false beliefs ('veritistic value') (*see* Truth and Credibility in Science). Social interactions, practices, and forces that influence – in a positive or negative way – the pursuit of truth include communicational acts, institutional structures that frame such acts (like universities, journals publishing peer reviewed articles, or conferences), speech practices of reporting and arguing, ways of access to different sorts of information (including internet resources (Goldman, 2006)), market mechanisms regulating the flow of speech, information technologies (Goldman and Cox, 1996), legal systems, and ways of disseminating information about electoral candidates.

One of the most important social aspects of science is the division of cognitive labor (Kitcher, 1990; Thagard, 1997). For instance, it will optimize the scientific pursuit of truth if different members of a scientific community pursue different strategies of solving a scientific problem, rather than all work on the most promising strategy. From this perspective, science can only make progress if it relies on a social consensus practice consisting, in its core sense, of individual practices common to all members of a scientific community. In a broader sense, the consensus practices include the exploitation of reliable scientific authorities, formal and empirical methodologies and background assumptions (Kitcher, 1993).

Another way of addressing the social aspects of science in a veritistic mood is to develop theories of cultures of knowledge. The starting point of such theories is the idea that cultures of knowledge have to be distinguished from theories and contents of knowledge. Classical theories of knowledge tend to provide definitions of knowledge articulating ideals of knowledge and the pursuit of truth. In contrast, cultures of knowledge are constituted by epistemic practices. Epistemic practices are collections of practices aiming at producing, selecting, organizing, and transmitting knowledge (true justified beliefs). They are a kind of culture if a culture is taken, in general, as a set of practices which are pursued by a group of people, which are taught and learned, handed over, institutionalized within this group, and whose exercise leads to a certain social status, e.g., to membership in a social community. To investigate cultures of knowledge, then, means to analyze the epistemic practices of a group of people and to explore the social realization of these practices. Asking for cultures of knowledge is an attempt not to ask simply for the social conditions in which theories did rise and fall, as traditional social epistemology did, but to look at the complex of epistemic practices, theories and ideals of knowledge, and their social conditions and realizations. The point is not to treat definitions of knowledge as mere ideological epiphenomena, but to relate them to epistemic practices and to relate this complex to its social environment (Detel, 2007; Fried, 2009). Contrary to what one might think at first sight (Longino, 1990, 2002), theories about epistemic practices and cultures of (scientific) knowledge and about the historical changes of such epistemic cultures are compatible with assumptions about a universal scientific rationality (Detel, 2009).

Basically, there is nothing wrong with veritistic approaches to social epistemology. This is not to say, though, that there are no open problems with this view. For example, one of the topics that need to be addressed is in which way the pursuit, not of true beliefs, but of justified beliefs can be socially

determined. In this context, pointing to reliable testimony has been, and must be, discussed (Fricker, 1995, 1998; Goldman, 2001; Lackey, 2006; Pettit, 2006). In addition, the historical change of epistemic practices and cultures of knowledge seems to involve a relativism of rationality and justification (Longino, 1990, 2002; but see Detel, 2009).

Nonveritistic Approaches to Social Epistemology

According to the nonveritistic approach to social epistemology, empirical, historical, and sociological studies of scientific practices show that science and scientific results do not depend exclusively on the objective external world which make scientific beliefs true or false, but rather also (or even mainly or exclusively) on social arrangements resulting from negotiations between scientists taking place in the course of scientific practices. The guiding idea is that science, scientific knowledge, and scientific practices are socially determined. It is in this sense that scientific knowledge is supposed to be socially constructed.

Social constructionists in the nonveritistic mood maintain three fundamental theses (Hacking, 2000):

1. Contingency thesis: Natural sciences could have developed in alternative ways. The way natural sciences have in fact developed is not inevitable, but was to a certain extent contingent (for an important historical case see Shapin and Schaffer, 1985).
2. Nominalist thesis: At most some individual things, but not facts or universals, can be taken to exist independently of humans and their social actions.
3. Stability thesis: Explanations for the stability of scientific beliefs must rely, at least in part (sometimes even exclusively) on social factors that are external to the internal criteria of theory choice maintained in modern natural sciences and articulated in rationalist philosophies of science.

Social constructivism is not a unique specified doctrine, however, but rather a bunch of related studies representing different versions of the general nonveritistic approach.

The earliest prominent version is the Edinburgh school of the sociology of science (sometimes called the strong program of the sociology of science) (*see* Strong Program, Sociology of). The proponents of this school start out by criticizing the Marxist sociology of science for the exclusion of mathematics and natural sciences as a proper subject of the sociology of science. The extended claim is that mathematics and natural sciences are socially determined too. Specifically, it is, according to the Edinburgh sociologists of science, not only the historical development of science, its rise and success, that is influenced by social forces; rather, it is the content of accepted scientific beliefs that is determined by social factors or social interests being involved in scientific practices. There are four methodological principle guiding this sort of social constructivism: (1) causality, i.e., exploring the conditions that causally bring about claims to a certain kind of knowledge. (2) impartiality, i.e., examining successful as well as unsuccessful knowledge claims. (3) symmetry, i.e., using the same types of explanations for successful and unsuccessful knowledge claims alike. (4) reflexivity, i.e., applying the theory to itself (Bloor, 1976/1992; Knorr-Cetina, 1981, 1982; Latour and Woolgar, 1986).

From their sociological studies the Edinburgh sociologists of science conclude that there is no definite unique set of rational methods that guide scientific practices and can be referred to in order to explain how scientific results and beliefs are established. Another result is that a sharp distinction between the context of discovery and the context of justification is not helpful in sociological investigations of scientific practices. In this way, the Edinburgh school rejects fundamental assumptions held by the traditional philosophy of science.

If scientific practices and the development of science cannot be rationally reconstructed, then the sociological analysis of scientific practice must basically be a causal explanation of belief formation and belief validation: it is supposed to show in detail how specific scientific beliefs are established as a result of a causal process proceeding from social conditions, social interests, and negotiations between scientists guiding the specific scientific practice under consideration (Kusch, 2002). Therefore, social constructivism is, in the view of the Edinburgh school, itself a kind of natural science. The domain of this sort of science is the set of all scientific beliefs that get accepted for the time being, independently of whether they are true or false and whether they ultimately prove to be successful or not. But social constructivism, as proposed by the Edinburgh sociologists, can also be formulated as a methodological claim mandating a naturalistic approach to scientific practices; as such, social constructivism is best understood as being part of a naturalized epistemology concentrating on the investigation of social causes of belief formation. In the methodological version, nonveritistic social constructivism does not seem to be committed to ontological claims; however, it remains committed at least to the epistemological claim that scientific knowledge cannot simply be seen as an adequate representation of the external objective world, but must rather be taken to be a result of an extremely complex process involving mainly and most importantly social causes. In this way, social constructivism is not only a form of antirationalism, but also a form of antirealism and in this twofold sense, a form of relativism (*see* Relativism, Cognitive; Relativism: Philosophical Aspects).

Another leading version of a nonveritistic social epistemology is the actor–network theory (Latour and Woolgar, 1986; Latour, 1987) (*see* Actor-Network Theory). The leading thought is that scientific knowledge is an effect of established relations between objects, animals, and humans engaged in scientific practices. An actor is, according to this theory, everything that in some causal way affects the production of scientific statements and theories: not only scientists and their actions, but also, for instance, background assumptions, methodologies, techniques, social rules and institutions, routines, experiments, measurements, and the appropriate instruments as well as scientific texts. For an entity to be an actor in this sense it is obviously not required to have contentful mental states and to be able to perform actions as a kind of behavior describable under some intention. Thus,

there can be many sorts of relations and interactions between actors; in particular, some actors can transform other actors (these transformations are sometimes called translations). A network is a set of actors such that there are relations and translations between the actors that are stable, in this way determining the place and functions of the actors within the network. Once a network has been established it implies a sort of closure that prevents other actors or relations from entering the network, thereby opening the possibility of accumulating scientific knowledge that is taken to be the result of translations within the network. Establishing a scientific belief or theory or fact comes down, from the point of view of the actor–network theory, to placing these actors in a stable network. In this sense, scientific beliefs, knowledge, and theories are taken to be constructed by translations taking place in established networks.

The actor–network theory shares a number of basic assumptions with social constructivism as conceived in the Edinburgh school. Thus, both approaches entertain a naturalistic account of scientific practices, do not presuppose a distinction between true or successful and false or unsuccessful scientific beliefs, and reject the possibility of a rational reconstruction of scientific practices and their outcomes. This is sometimes declared the end of knowledge (Fuller, 1988, 1993).

Nonveritistic social constructivism does not use the term *construction* in the literal sense that some things, and especially facts of the external world, get constructed out of some other things in the course of scientific practices. The crucial idea of a (social) construction of scientific knowledge is, rather, that the process and, indeed, the history of scientific belief formation should not be analyzed in terms of a rational reconstruction that tries to show how the methods of science continuously increase the probability that scientific beliefs are adequate representations of an independent external world. Rather, the process and history of scientific belief formation should be modeled in terms of a number of different factors (including rules, techniques, routines, institutions, and other relations) that affect scientific belief formation – mostly in causal ways that can be studied empirically and naturalistically (*see* Knowledge, Sociology of).

One of the most debated applications of social constructivism is the claim held by many feminists that gender is socially constructed (Anderson, 1995) (see *Gender Studies*). Originally, the most prominent feminist theories introduced a distinction between a naturalistic notion of sex and a social notion of gender to denounce all attempts of deriving properties of gender from properties of sex as mere constructions of gender that do not refer to reality. More recently, in some postmodern feminist accounts of sex and gender, it is also the very distinction between sex and gender, and thus, sex itself, that are supposed to be socially constructed (Lorber and Farrell, 1991; Alcoff and Potter, 1993; Potter, 1993; Charlebois, 2011).

A well-known general objection against nonveritistic approaches to social epistemology is that the leading studies use empirical, sociological, and historical evidence to justify fundamental and far-reaching claims that are supposed to debunk the epistemic authority and universal rationality of the sciences. Obviously, in doing so they rely themselves on exactly those scientific methods they try to debunk. For instance, the claim that "there are no context-free or super-cultural norms of rationality" (Barnes and Bloor, 1982, 27) can only be defended by carefully examining the historical and cultural evidence as well as by applying the hypothetical-deductive method.

Radical (Strong) Social Constructivism

Strong Social Constructivism and Ontology

One of the crucial claims of nonveritistic social epistemology is that mathematics and natural sciences are socially determined too. It is this view that proves fundamental for the further claim of many social constructivists that, in a sense, the world as such is socially constructed. Some constructivists focus not on belief formation, but rather on scientific facts: they want to know in which way such facts are hardened, i.e., get accepted as facts by all researchers in the field (Latour and Woolgar, 1986). It is precisely by shifting the focus from beliefs to facts that some social constructivists are inclined to entertain an ontological version of social constructivism that sees scientists as making up scientific facts.

Proponents of this sort of radical social constructivism rely sometimes on the view (entertained by many different philosophers) that scientific facts are supposed to be what accepted scientific beliefs are about – roughly the content of statements showing up in established scientific textbooks on the field (Quine, 1969). On this view, radical social constructivism has idealistic implications only if scientific facts are understood in a strictly realistic fashion – roughly as the way things are independent of the way we take them to be. Radical social constructionists reject this ontological realism as naive (Bloor, 1996).

From this point of view, proponents of nonveritistic approaches to social epistemology often derive a radical constructivist stance. For instance, according to the actor–network theory establishing a scientific theory comes down to locating all things that have an impact for the production and acceptance of scientific theories (the so-called actors) in a stable scientific actor–network. However, these actors are supposed to include facts and external things. If an actor–network changes, all actors (among them facts and external things) change too. In this sense, not only scientific beliefs, knowledge, and theories, but also facts are taken to be socially constructed by translations taking place in actor–networks.

However, the ontology of strong social constructivism is clearly misguided. Even if one rejects naive ontological realism and concedes that scientific facts are supposed to be what accepted scientific theories are about (as for instance Quine, 1953 did), it does not follow that scientific agreements literally produce scientific facts, but only that scientific agreements justify hypothetical existence claims about some parts of the world. If scientific theories change, then it is not parts of the world but only some of our hypothesized existence claims that change too.

Strong Social Constructivism and the Social

Some radical constructionists maintain that constructivism in the sense of the actor–network theory is social not in the strong sense that social forces that are presupposed to exist largely

independently of scientific practices and have a causal impact on these practices – mainly for the reason that the social is barely better understood than the natural. Rather, constructivism is taken to be social only in the weak sense that as a result of processes taking place in networks as a scientific claim about a distinction between the natural and the social, and so about the function of the social for scientific practices, can eventually be developed (Pickering, 1984, 1992). This branch of radical constructivism rejects the idea of a social determination of scientific knowledge prominent in veritistic approaches to social epistemology as well as, for instance, in the Edinburgh school. This thought involves a confusion, though. It implies the absurd demand that a scientific theory may never rely on claims or distinctions (such as the distinction between the natural and the social realm) that have already been themselves socially constructed.

Finally, among radical social constructionists one might distinguish causal constructionists holding that human activities cause and maintain facts about the world (including scientific facts) from constitutive constructionists holding that facts about the world are really nothing else than human activities (Kukla, 2000). It is not clear, however, whether the leading proponents of strong social constructivism are causal or constitutive constructionists.

Constructivism about the Social (Social Ontology)

Verististic, nonveritistic, and strong social constructivism rely not only on a notion of the social, but also on the assumption that the social realm (including social actions) can be taken to be given. But these kinds of social constructivism neither provide a clear definition of the social nor do they explain in which way social items may exist and so be taken as given for certain theoretical purposes. This is, however, what social ontology aspires to, i.e., social constructivism in then sense of a construction of social entities like social actions, social groups, social status, or social institutions.

Constructivism and International Relations

One of the most recent specific examples of social ontology is the social-constructivist theory of international relations (IR). Traditional IR-theory (in particular neorealism) explores mainly in which ways power-items (for example, military forces or economic capacities) determine international relations, notably international balance of power and interaction between states. Insofar as military forces, economic capacities and similar entities involve a material component, the social-constructivist IR-theory takes traditional and especially neoliberal IR-theory to be a materialist theory. In contrast, social-constructivist IR-theory urges that international relations are basically social, not material. They are a human creation relying on human ideas guiding political actors moving in the international scene. In this sense, international relations are socially constructed: "The claim is not that ideas are more important than power and interest, or that they are autonomous from power and interest. The claim is rather that power and interest have the effects they do in virtue of the ideas that make them up. Power and interest presuppose ideas…Let me [propose] a rule of thumb for idealists: when confronted by ostensibly "materialist" explanations, always inquire into the discursive conditions which make them work" (Wendt, 1999, 135 f.).

As this quote from one of the leading social-constructivist IR-theorists shows, the position is sometimes not sufficiently carefully articulated. In particular, some of the formulations come close to an idealist stance involving the claim that ideas 'makeup' power, interest and, indeed, international relations, and, furthermore, that international relations depend exclusively on discursive conditions and "exist only as an intersubjective awareness among people … It is a set of ideas, a body of thought, a system of norms, which has been arranged by certain people at a particular time and place" (Jackson and Sørensen, 2006; ch.6, 162).

But there are also proponents of social-constructivist IR-theory who emphasize that it is not only, and not even prominently, ideas but rather social norms, rules, and relationships we have with others that determine political behavior, "endow material entities with meaning and purpose and provide us with ends to which power and wealth can be used" (Finnemore, 1996, 128). Still, even in these less idealistic accounts of social IR-constructivism a clearly articulated relation between ideas, actions, institutions, interests, and power is missing. It is general social ontology that presents a picture that is, in this respect, much more transparent.

Constructivism and Social Ontology

In one of the most recent developments of social constructivism, leading proponents of the Edinburgh school try to exploit the thought that scientific knowledge is, after all, something like an institution and that institutions in general are constructed by humans (Bloor, 1996). It seems to follow that scientific knowledge is, as being constructed by humans, socially constructed. The idea that institutions are constructed by human persons is part of what is often called the intentionalist program of social ontology. The aim of this program is to clarify the ontological status of social entities, i.e., of social groups, social status, and institutions. The fundamental claim is that it is on the basis of collective mental states and of actions describable under collective intentions that social entities come into existence and maintain an ontological status. That is to say that human beings produce, that is literally construct social entities by having specific contentful thoughts and by performing certain intentional actions (*see* Cooperation: Sociological Aspects).

It is obvious that this approach is a sort of social constructivism in the sense that it is a theory about the construction of the social. This construction is itself held to be social insofar as it consists largely of normative interactions between humans. But it must be emphasized that this sort of constructivism is restricted to the realm of the social, that it presupposes a sharp distinction between the natural and the social, and that it has nothing to say about the construction of natural facts or physical entities. Most importantly, though, the intentionalist program relies on an intentional and normative vocabulary. In all these respects the program differs fundamentally from traditional versions of social constructivism.

Basically the intentionalist program of social ontology is an individualistic account of the social. It relies on the notion of an action as behavior that is describable under a specific contentful intention. Actually, it is the intention that epistemically identifies and ontologically individuates the given behavior as a certain action. One of the crucial theoretical moves is to introduce notions of collective intentions, beliefs and actions. The first step is to assume that for some persons to be socially related in a specific way is to be treated by most of the other members of their society as being related this way. Social relations are taken to imply rules as well as certain rights. In general, therefore, to treat some persons to be socially related in way S is to treat them as being entitled or committed to perform actions according to the rules and rights derivable from S. One of the next important moves is to introduce the notion of a collective attitude (or, as it is sometimes called, a we-attitude) and, in particular, the notion of a collective intention to perform a specific action. Roughly speaking a person P as member of a set S of persons has a contentful collective attitude of the sort A iff (1) P has the A-attitude herself, (2) P believes that every other member has the A-attitude, and (3) P believes that every other member M of S believes that every member of S other than M has the A-attitude. In particular, if a number of persons P_i intend to perform action A together or collectively, then it must be the case, in addition to (1)–(3), that every P_i intends to perform A by performing a specific action A_i as her specific contribution to the performance of A such that P_i thinks that A_i is necessary for A and results, together with the other specific actions A_j intended to be performed by the other P_j, in performing A, and that P_i believes that the other P_j intend to do the same thing and believe themselves that every other person intends to do the same thing. On the basis of these notions it can be defined that (a) that a number of persons P_i have the collective intention to perform action A iff each P_i has the collective intention to do A by performing a specific A_i, in the sense just explained; and P_i perform a collective action A iff A can be described under some collective intention of the P_i. One might then suggest that a number of persons P_i represent a social group iff they share a collective attitude. Finally, let MR be a set of semantically consistent rules R_i such that a number of persons collectively treat an X as a Y by following R_i, then MR is, in the most basic sense, an institution. In particular, if MR is the set of rules according to which scientific results and scientific knowledge are established, and if the persons in question are trained scientists, then MR is an institution of epistemic or scientific practices, and in this sense, scientific knowledge might be called an institution that is constructed by intentional acts of human beings (Gilbert, 1989; Pettit, 1993; Searle, 1995, 2011; Tuomela, 1995, 2007).

This line of argument is a rough sketch that by no means exhausts the theoretical complexity of the intentionalist program of social ontology. For instance, something has to be said about the mechanisms of the formation of collective attitudes to account for the stability of social groups and institutions; at this point, a theory of consensus and a theory of power has to be implemented into the general account. Furthermore, social ontology has to be related to scientific practices in the social sciences (Mantzavinos, 2009).

In any case, even a rough sketch of this sort of social ontology shows in which way, to put it very generally, collective minds and collective actions can be thought to bring into existence, and to keep in existence, and thus to construct, social entities in a fairly literal manner. And it becomes also clear how and why traditional social constructivists might be inclined to render their position more precise by exploiting the intentionalist program of social ontology. This program is a philosophically sound approach. It makes evident, though, that the collective human mind and collective human actions construct social facts in ways in which they don't construct natural facts, i.e., parts of nature governed by natural laws.

Nonveritistic and strong versions of social constructivism tend to downplay this distinction, and this strategy is certainly a fundamental flaw. Another problem with these versions is that they seem to commit themselves to relying exclusively on a causal, physicalist vocabulary. While it certainly makes sense to examine whether a purely naturalistic account of epistemic practices might be fruitful, it does not follow from this strategy, even if it proves fruitful, that intentionalist strategies must be excluded. On the contrary, it is doubtful whether epistemic practices can be adequately described without using also intentionalistic and normative vocabulary. Finally, it is hard to see how nonveritistic social constructivists can overcome Davidson's point that interpretation theory must be part of theorizing about epistemic practices which implies, in turn, that a notion of rationality cannot be excluded and that, at the most fundamental level, the notions of rationality in different epistemic practices must converge. Obviously, this insight is inconsistent with an unqualified contingency claim and relativism about rationality so central for nonveritistic and strong social constructivism.

Abstract

One of the many founding concepts of contemporary social science that arose during the Enlightenment was the idea that society could control the behavior of its citizens by using formal mechanisms of social control. Theoretically, by manipulating the magnitude of punishment or pain guilty persons would experience for their deviant behavior, society could stop offenders before they acted. More specifically, since offenders acted in their own best interests, they would think about the costs and benefits of their behaviors prior to acting. Through punishment, society could make the costs of deviant or criminal behavior outweigh whatever benefits miscreants might otherwise accrue. Moreover, this would translate to more general societal deterrence if the punishments individuals received were certain, swift, and severe. This article reviews the history of these concepts through to the present day.

One could argue that humans live collectively. Is it because we are social creatures? Or, do we need each other to survive the harshness of life on earth? It is likely to be some combination of desire and necessity as well as a variety of additional explanations. What is important here is that humans have benefited from the formation of societies and communities in many ways (e.g., the division of labor, collective efficacy, protection from outsiders, in-group processes to name just a few). Indeed, early philosophers noted that the need to form societies and communities provided so much benefit that people were willing to make sacrifices in order to belong. Typically, when humans come together in groups, these societies/communities necessarily establish norms and values in order to make life more predictable and navigable. Of course, the mere formation of norms almost assures that there will be individuals, who, for whatever reason are unable or unwilling to meet the standards and expectations of their fellow affiliates, and society must deal with these nonconformists. Many academic disciplines have proffered explanations for deviance and social control in order to better understand this seemingly inevitable group phenomenon. Sociology (and its subfield of criminology) is one such discipline. Early on, the study of deviance and social control was seen as fundamental to the understanding of society. Threats to morality and the social order, and institutional processes and efforts to control such encroachments were viewed as vital topics for sociological investigation and discourse. Later, scholars eschewed the study of deviance, ironically viewing the intellectual discourse surrounding deviance and social control as not much better than the nonconformists with which they concerned themselves. As time has passed, the relevance of deviance and social control has returned, and the theoretical explanations for them have become more and more sophisticated. What follows is a brief treatise on the history and development of sociological discourse pertaining to deviance and social control.

Prior to the formation of the discipline of sociology, there were plenty of intellectuals interested in explaining deviance and social control. Early primitive people lived in a world where behavior and events were seen as being the result of otherworldly powers. Plagues, floods, and famines were seen as divine punishments (Newman, 1978). Religious leaders performed rituals in order to appease these vengeful spiritual powers. Deviance was seen as the result of possession, and persons who were suspected of deviant behavior were put through 'trials by ordeal' in order to determine their guilt or innocence. Individuals who survived these ordeals were innocent and those who did not survive were guilty, but they were also dead so the situation had been resolved (e.g., A woman suspected of being a witch was tied up and thrown into the water. If she floated she was not a witch; if she sunk was guilty of witchery). Social control, then, in this environment was more about punishing guilty miscreants and ridding society of them (Newman, 1978).

During the Enlightenment, intellectual discourse shifted and philosophers began to view human behavior and social events as being the result of freethinking and free will. Beliefs such as humans being rational, capable of understanding themselves, and acting in their own best interests took center stage, thereby shifting views about deviant behavior from being otherworldly to the result of clear and calculated thinking. This, obviously, represented a huge change in the underlying philosophy of social control and what societies could do to minimize unacceptable and harmful behavior. From this view, scholars from different paradigms formulated theories that explained deviance and social control using different conceptualizations and perspectives.

One important paradigmatic shift that developed was the idea that society could, through serious contemplation, control the behavior of its citizens by using formal mechanisms of social control (Beccaria, 1764; Bentham, 1789). Theoretically, by manipulating the magnitude of punishment or pain a guilty person would experience for his/her deviant behavior; society could stop offenders before they acted. More specifically, since offenders acted in their own best interests, they would think about the benefits of their behaviors prior to acting. Through the threat of punishment, society could force offenders to consider the costs of their behavior whereby (if assessed correctly) the pain or cost of committing a crime slightly outweighed the benefits of it. Moreover, this would translate to more general societal deterrence if the punishments individuals received were certain, swift, and severe. With this perspective, then, deviance was basically those behaviors that were illegal,

because social control was more formulized and was handed out by the State.

This view that society could impact the behavior of individuals through formal social control mechanisms encouraged further research on how groups or communities could positively influence the behavior of their members. Sociologists saw social control as encompassing all those social practices and arrangements that contributed to the maintenance of social order and conformity among social group members, both formal (e.g., arrest) and informal (e.g., shunning). Early theorists viewed these processes as a reflection of social consensus, thereby characterizing social groups as harmonious, consensual, and concordant. Scholars in the late nineteenth century also viewed social control as the fabric of 'organized society.' Social control, then, encompassed the tools through which society formed and maintained harmony.

One problem, however, with restricting the study of deviance to illegalities is that in communities and neighborhoods, people have varying views about deviance. So, researchers must contend with the varying views that people have about it. Because of this, criminologists often find it difficult to work within a legal framework. There are two primary reasons for this. (1) Often what distinguishes whether or not a particular behavior is legal or illegal is based on a technicality that likely has no bearing on causation (e.g., manslaughter vs tragic accident is often a matter of perspective). (2) The law groups various behaviors together that are not similar in terms of causation (e.g., serial homicide, which includes serial murder and mass murder) (Vold, 1958). For this reason many criminologists focused on the 'nature' of a particular behavior rather than the legal definition of it. For example, Hermann Mannheim (1965) posited the view that criminology should study all antisocial behavior, while Edwin Sutherland (1934) viewed crime as behavior that was harmful to society. Thorsten Sellin (1950) defined crime as the violation of conduct norms, while Schwendinger and Schwendinger (1977) thought of crimes as violations of human rights.

Continuing, deviance theorists often focused on the violation of cultural, group, or societal norms, rules, and expectations. Where they differed was the formulation of those norms and expectations. And, an important distinction among scholars was the difference between 'primary' and 'secondary' deviance (Lemert, 1951). Primary deviance was committed by a wide range of individuals in any population, and the causes of it vary widely. Secondary deviance was deviance that was committed due to the stigma associated with certain actions, and the processes that society used to punish and control it. What most scholars agreed on, however, was that there was nothing constant about social views of crime or deviance, so pinpointing certain actions as criminal or deviance over time was a fruitless endeavor. In spite of these definitional difficulties, early sociological deviance theorists typically saw deviance as the result of 'pathologies,' or things that were wrong with individuals, communities, or societies.

Alongside the development of the perspective that humans had free will was a methodological shift in the science of deviant behavior. Auguste Comte (1865), regularly viewed as the founder of the discipline of sociology, wrote less about deviance and social control, but extensively about positivism as an epistemological perspective. Many theorists were influenced significantly by Comte. And, this shift in methodological stance marked such a tremendous change in the frame of reference of theoretical discourse that it might be likened to a revolution. In the earliest years of sociology, then, the study of deviance was primarily the study of observable or empirically based causes of crime and deviance.

One example of early positivism is Cesare Lombroso (1835–1909) who is viewed as the father of the positivist school of criminology (Lombroso, 1876). Initially, Lombroso examined several hundred Italian criminals and found they had physical characteristics that suggested inadequacy and degeneracy. Such characteristics were asymmetry of the face; abnormally large or small head size; excessive jaw and cheekbone dimensions; ears of unusual size (e.g., small, protruding from the head); abnormal nose (e.g., twisted, upturned, flattened, beaklike, or having swollen nostrils); fleshy, swollen, and protruding lips; and pouches in the cheek like those of some animals. These physical characteristics resembled the appearance of lower or more apelike ancestors; thus the individuals having them were assumed to belong to these earlier evolutionary forms. Even though Lombroso's theory of the atavistic criminal has since been debunked, he is important because he exemplifies early efforts to combine theory and science, the scientific generation of facts that can be explained by theoretical interpretation. Additionally, later in his career, he began including psychological and environmental factors into his deliberations on the criminal man, thereby incorporating multiple factors into his theoretical development.

Another example of positivism was one that considered more sociological explanations. During the late 1700s to early 1800s societies worldwide were undergoing massive transformations, and these changes led theorists to consider what changes in deviance would occur due to emerging social change. To elaborate, during the mid-1800s until the mid-1900s American and European sociologists were studying the large-scale social changes that were taking place (Websdale, 2010). These changes included such immense happenings as urbanization, industrialization, capitalism, immigration or emigration, family, and community. These massive social changes influenced societies, communities, and individuals in equally large parts. For example, as the world became more industrialized, more and more young adults left their families' farms and moved to the city in search of wage labor. This increased the amount of urbanization, and population density, which, in turn, changed the way people thought of 'community.' The influx of immigration also changed the face of communities and neighborhoods and cultural heterogeneity increased. As more and more people were uprooted from their traditional lives, many customs fell to the wayside, and people were thrown into a new normless society. In the more traditional communities, family depended on their neighbors for food or items they could not produce themselves. In the city, people did not necessarily know their neighbors or interact much with them. And, men and women were both seen as making valuable and necessary contributions to the functioning of the family. But, with the onset of city life, the close-knit communities that characterized farming areas fell to the wayside and the economy shifted from one where a man worked a job that (literally) provided the food and other items his family needed to one where having a job that paid

money was a necessity. This, of course, changed traditional gender roles when men left the home to work, and women stayed at home to work. Another change that confused gender norms was that as more young men got jobs in the cities, the ways in which they could express their masculinity had to change also. Additionally, the extended family broke up and the nuclear family became more common. This led to a reduction in the number of children couples had because children became economic liabilities and no longer free labor. All of these changes were happening in societies all over the globe, and even though they brought confusion, anger, turmoil, uncertainty, and even an increase in the amount of deviance and crime, most people adapted and conformed to the new social norms and values.

More sociological causes of crime emerged in Europe during this time as systematic registries of births, deaths, and other official records were collected, maintained, and were seen as relatively accurate. Sociological positivists examined the relationships between crime, poverty, economic depression, malnutrition, low intelligence, resentment, unemployment, and relative social inequality, and found that relationships, while not corresponding 100% of the time, these relationships did, indeed, provide partial explanations for criminal or deviant behavior. One issue that arose among these researchers was how to interpret these relationships. For example, some saw poverty as a cultural or learned helplessness that causes crime, while others viewed poverty as a structural limitation that caused deviance and other socially unacceptable behavior.

This search for the pathological causes of crime, however, grew unsatisfying for many sociologists, who began to delve into other ways to explain crime, criminal behavior, and other forms of socially harmful conduct. By focusing on only those pathological characteristics of individuals, some emerging sociologists felt that many potentially relevant social factors were ignored. It was in this climate, the Chicago School of Sociology was born. Researchers at the University of Chicago in the early to mid-twentieth century aggressively emphasized a break with prior (whom they saw as naïve) theorists who were too narrowly focused on individuals and pathologies. Chicago academics saw the environment as a crucial location for research, and the research to be necessarily done involved more rigorous empirical research such as life histories, ethnographic field studies, and census data.

Early on the Chicago School established its theoretical base as the city. Scholars in Chicago such as Robert Park et al. (1925), found the urban environment, with its tremendous diversity, locational and structural patterns, and varying cultures and lifestyles to be infinitely interesting and researchable. Additionally, they viewed areas within the city as having their own character, functions, and populations. This led to the development of their main theoretical proposition which was that cities were arranged in concentric zones of social life. The central business district made up the center zone of social life in the city. It was surrounded by the 'zone of transition,' which was an area inhabited by the poor, the marginalized, and the recently arrived. Next to the transition zone was a concentric layer of working class residents, followed by the residential zone, made up of people who had moderate amounts of money, regular work, and greater ownership of property. Finally, there was the commuter zone, where people who wanted to flee the largeness, density, and diversity of the city lived.

Clifford Shaw and Henry McKay's longitudinal study of juvenile delinquency in Chicago bore out this zonal perspective (1942). Using a very early sort of mapping analysis, Shaw and McKay constructed a series of maps of Chicago and mapped the residences of juvenile delinquents and various other community characteristics (e.g., the location of demolished buildings, the incidence of tuberculosis, and the residences of truants). They then constructed rate maps which showed the percentage of the population that was delinquent based on the other mapped characteristics. The analysis of these maps indicated several important things: that areas with the most delinquency did not necessarily have the most delinquents; the areas with the greatest rates of social problems and juvenile delinquency tended to be concentrated close to the center of the city; the areas that had the highest rates of juvenile delinquency were located within or immediately adjacent to areas of heavy industry or commerce. These areas also had the highest rates of structural degradation, population decline, low economic status, high percentage of families on welfare, low percentage of families owning their own homes, high infant deaths, high rates of tuberculosis, and high rates of adult criminality. In addition, these areas also had high proportions of black and immigrant residents. Finally, these patterns held even when the ethnic composition of the transitional zone changed (e.g., from Irish to Puerto Rican). These findings provided solid evidence that delinquency was influenced, at least in part, by location and urban culture, and not completely by individual pathologies. Deviance was thus viewed as a product of social disorganization.

Another distinction with the Chicago School was that they not only had a strong organizing theoretical framework, but they had an institutional base. This led to an emphasis on training researchers to continue their theoretical development via continued empirical research. So, describing and understanding the underlying dynamics of social life in the zone of transition was another aspect of the theoretical discourse during the heyday of the Chicago School. The graduate students of these eminent scholars were tasked with going into these deteriorated but highly diverse neighborhoods and gaining access to the worlds of the poor, powerless, and exotic and telling their stories (often in miniscule detail) through ethnographic explorations. Such views characterized many of the books published during this time, which included ethnographies of gangs (Thrasher, 1929), organized crime (Landesco, 1929), the hobo (Anderson, 1923), the prostitute (Reckless, 1933), the taxi-dance hall (Cressey, 1932), the rooming house district (Zorbaugh, 1929), the immigrant neighborhoods (Thomas and Zanaiecki, 1920), and blacks (Drake and Cayton, 1945), just to name a few. This concentration on the transitional zone as being distinct from other zones led to the central underlying theoretical theme, which was that different areas of the city were organized differently.

The white male scholars of the Chicago School interpreted this differential organization as less organized than other zones, and thus began social disorganization theory. This theory, which is still popular today, emphasized that neighborhoods with social characteristics such as lower economic status, lower home ownership, higher percentages of the population that are minority or immigrant, higher population density,

more vacant or boarded-up buildings, trash and litter on the street and in yards, higher amounts of victimless crimes (e.g., prostitution, drug, or gun sales), higher amounts of vandalism and property damage, unkempt lawns, and fewer neighborly interactions were neighborhoods where residents were unsatisfied with their surroundings, were planning to leave as soon as money allowed, and cared less for the upkeep of their community since they had less 'stake' in it. Because of this, these residents were also less collectively oriented, so their abilities to rid the community of negative influences was compromised, and they were unlikely to look out for each other and notice outsiders in their midst (Sampson, 2012). This more apathetic attitude showed in the condition of the neighborhood, and as a result, crime and other forms of deviance flourished.

One of the common criticisms of the Chicago School, however, was that its theorists used their own moral judgments to explain their findings rather than sociological analysis. For example, some critics argued that the social world of gangs, prostitutes, and those who frequent taxi-dance halls was not disorganized, per se, it was just organized differently. In this way, than, it was likely that neighborhoods with greater amounts of crime were not so much disorganized as they were differently organized, in ways that allowed crime or deviance to move in and stay.

Another perspective that grew from the idea that humans had free will, was the Functionalist view of crime and deviance which maintained that crime was more a way of life for some groups. In this way, crime and deviance were 'natural' responses to group and social pressures, and criminals and deviants were normal. As the founder of this perspective, Emile Durkheim (1893, 1897) theorized that among the many social institutions that were functional for society, deviance was an institution that was more complex. Even though deviant behavior could cause harm to individuals, it was still functional for society because it forced people to confront their views about what was acceptable and unacceptable and make decisions about what actions would be condemned and which would be absolved. Durkheim argued that without negative behavior, members of society would not have values or morals and there would be a breakdown in the ability of society to regulate the natural proclivities of individuals. This, in turn, would lead to anomie, or a feeling of being not grounded or unconnected.

Subsequent functionalists used these theoretical principles and developed what is known today as strain theory. Strain theorists, such as Robert K. Merton (1938) and Marshall B. Clinard (1957) proposed that each society has at least several social generated pressures or strains that cause criminal behavior. Not all groups feel these pressures equally, but the groups that experience them the most severely are the ones that are most criminal or deviant. This line of theoretical discourse explains that every culture has some important values or goals that are accepted by nearly everyone. There are also institutionally accepted ways or means of achieving these key goals. However, the structure of most societies does not allow everyone to actually attain these well-accepted goals. So, many will be unable to meet cultural expectations, and this will cause anomie among those individuals as well as in groups where many members fall short. This is what leads to strain. Merton argued that there are various ways that individuals can respond to anomie, depending on that individual's or group's attitude about the cultural goals and means. In highly stable societies, individuals will continue to conform, which is to say they still want to meet cultural expectations using socially approved means. Most crimes emerge from the response called innovation. Persons responding this way continue to want to achieve the cultural goals, but find they are unable to do so using acceptable social means, so they innovate (usually by doing something illegal). Some individuals will use a ritualistic response, which is when they continue to support cultural goals, but essentially give up on ever achieving them, and just go through the motions. Retreatists respond by dropping out of the whole game altogether. Those who choose this method of adaptation are typically psychotics, outcasts, vagrants, drunkards, and drug addicts. Rebellion is the last possible response to the problem of anomie. Here the person responds to his failure and frustration by replacing the values of society with new ones. These new values may be political (over throwing the government), religious (seeking a new state of spiritualism), or any number of other possibilities. But, in the end the rebel ceases to be a part of society and lives with an alternate culture, which is likely to be seen as deviant.

Strain theory has segued into subculture theory and is used to explain social groups that are deviant or criminal. For example, theorists explain gang formation as a collective and innovative solution by a group of underprivileged youth (Cloward and Ohlin, 1960). A group of religious outcasts responds with rebellion and physically removes themselves from society in order to relocate to the mountains of Idaho. A recent group of immigrants that is unable to find adequate work and housing after entering a country forms a community and economic enclave within an urban area where its members can work, live, express their unique cultural beliefs, and do not have to interact much with the larger society.

As a competing perspective, French sociologist Gabriel Tarde (1843–1904) expressed the notion that the great level of harmony in society was as equally worthy of study as penal philosophy (1890). More specifically, Tarde observed that most citizens' behavior was congruent with social norms and values, suggesting that social control strategies were fairly successful. For example, when considering deviance, Tarde wrote that the more interesting sociological puzzle was how people came to live together closely and in harmony. In other words, what might be equally, if not more interesting than explaining nonconformity was to explain such high levels of conformity.

So, even though deviance was an interesting sociological phenomenon, what followers of Tarde found equally compelling was the question of why so many people were cooperative, conforming, and 'normal,' even in times of social upheaval. Scholars during the early twentieth century wondered what could account for the reemergence of stability and harmony in the chaotic modern world (for a discussion of this issue see Buzan and Lawson, 2014)? And, given that the formal instruments of social control (e.g., police, governments) were not the likely answer, because social control could be created and maintained without the use or threat of force, what institutions of society were the primary contributors to social stability?

It is here that sociology provides an assortment of answers. Religion, education, family, the whole apparatus of socialization, politics, the military, and the reestablishment of social norms and values were some of the social institutions that theorists looked toward to understand both deviance and conformity. This perspective also shaped a long-standing disposition of sociology which is to analyze biography and history in order to better understand and provide solutions to social problems (Mills, 1959). More current scholars of this paradigm suggest that within these social institutions, people with a 'stake in conformity' were not deviant (Toby, 1957). The idea here is that most people's behavior is controlled through informal social control (e.g., neighbors and communities issuing 'in-group' or 'out-group' status or glares, exclusion, and disapproval). Because we are social beings, we want to fit in and be a part of the group. If that is threatened, we conform to norms and values in order to be accepted (Nye, 1958). Travis Hirschi (1969) provided an explanation for why people have a 'stake in conformity' by noting that there are four elements that increase the social bonds people have with the members of their families and communities. These elements are having an *attachment* (e.g., affectionate toward, sensitivity to) to others and their communities, being *committed* to conventional society (e.g., attending church, doing well in school, getting a job), *involvement* in conventional activities (e.g., playing on a sports team after school, joining the PTA), and *belief* in obeying the laws.

Another paradigmatic development that was occurring alongside the development of the Chicago School maintained its methodological emphasis on observation, but moved to the forefront the fluidity of deviance and social control. Among these Social Reaction theorists were Edwin Lemert (1951), Howard S. Becker (1963), and Erving Goffman (1959), all of whom became increasingly concerned with the process of becoming deviant; particularly the part played by official institutions of crime control and community informal social control. The theoretical gist here is that individuals who commit a crime or who are deviant once or twice (often unknowingly or with only minor transgressions) are officially labeled deviant, stigmatized by their communities, and become ignored and marginalized. This process often results in a continuation of deviant behavior rather than desistance, because the individual has developed the identity of deviant (or criminal), and becomes anomic and disconnected from society. So, deviance is largely defined by the stigmatizing and punitive reactions of others. This theoretical discourse, while originally ignored, became influential in the 1960s as some groups' cultural beliefs included ideas that governments and the rich had the power to impose their definitions and lifestyles on to the rest of the members of society. These new beliefs likely came to pass as a result of individuals who protested the war were attacked by law enforcement officers, and the emerging subcultures of greater drug use and free sexual expression were frowned upon by more 'respectable' societal members.

Social reaction theory's intellectual roots are the symbolic interactionist view of society. Here, the theoretical essence is that of dramaturgy (Goffman, 1959). Metaphorically, people act out their lives on a stage in front of an audience and they manipulate the audience's view by using or omitting various props, language, and settings to establish an impression. The audience, in turn, sees the props, is aware of the setting, and listens to the actor's use of language and forms an impression. Dramaturgy, then, is a two-way street, and is not always predictable. The actor may attempt to control the impression the audience has of his/her, by using a particular prop, but the audience may have a different association with that prop, thereby forming a different impression than what was intended. These symbolic interpretations are so strong that individuals often behave toward others according to their beliefs about these others. For example, Social Reaction theorists have discussed the impressions society has of the blind, the disfigured, stutterers, strippers, prostitutes, perverts, addicts, alcoholics, the unwashed, and the unwed (particularly mothers). The blind, for example, indicate that people often yell at them, apparently thinking if they are visually impaired, they must also be hard of hearing. Additionally, many people think that strippers, prostitutes, and unwed mothers are morally deficient, preferring to focus on the symbolic meanings of their observable actions rather than considering their hard-luck circumstances. Many researchers have looked at common educational practices that illustrate the bureaucratic process that labels certain children 'handicapped' or 'slow' and then ushers them into special education programs.

This theoretical discourse is easily applied to deviance. People hold many symbolic beliefs about those who behave unconventionally. Therefore, once someone has been deviant (primary deviance), the official processing that occurs, and this leads to stereotypical labeling. Deviant individuals, then, are viewed as moral reprobates, are shunned, excluded, marginalized, and ignored. This leads to a disconnection from society and further deviance (secondary deviance). This process can also take place on a more informal level. For example, if a boy is caught smoking marijuana in his neighborhood, it may happen that his neighbors will begin to think of him as a 'druggie' and stop letting him play with their children, get worried when he is around, and cross the street to avoid him when they are walking. This, in turn, would cause that boy to lose his bond with members of the community and feel isolated from them.

In keeping with this perspective on the world, the methods of research by these sociologists were to emphasize *Verstehen* (Weber, 1946). So, greater understanding could only be had when theorists examined deviant persons and groups from their own points of view. Researchers, then, who attempted to systematize or generalize their findings on unconventionality, were to be distrusted.

A final paradigm developing from early criminologists was heavily influenced by Karl Marx (1848). Theorists of this bent, such as George Vold (1958), Richard Quinney (1970), Jeffrey Reiman (1979), and William Chambliss (1973), drew on the politics of Marx to establish the foundation for their theories of crime. Marx argued that in the organized capitalist state the economy was controlled by the owners of the means of production. The workers' interests were not represented, and the only way the workers could gain any independence from the power of the owners was for the state to take over the means of production. Only when the state was in control would all

citizens' interests and needs be accommodated. Sociologists in the 1970s and later, particularly, were greatly influenced by the distrust of those in power and the assertion that crime and deviance were a result of social authority and labeling. This perspective harkens from the conflict approach to understanding society, and these theorists used radical discourse to suggest that the government itself was actually the cause of crime. The State caused criminal behavior because of its unequal treatment of social minorities, and its self-perpetuating goal of keeping the rich in control of the government and economy and the poor downtrodden and demoralized. Here, then, deviance is variable, as it reflects the opinions of the group that is in power. And, social control is used by those in power to keep down those who are not.

Scholars took a number of directions when applying Marx to the study of crime, deviance, and social control. Sellin (1950) suggested that conflict would arise when cultural subgroups' values and norms collided. As society became bigger and more complex, this collision would be inevitable. Within simple societies, cultural values and norms often become law and represent a consensus in society. But, as society grew and became more complex, subgroups with cultural distinctions would clash and the more powerful subgroups would emerge with their values and beliefs represented in law, while the norms and values of other less powerful cultural subgroups would become illegal or deviant. An extension of this thesis was the proposition that groups in society are always striving for or attempting to maintain their positions of power. One way that more powerful groups kept their positions of dominance was to define others groups as unconventional and in need of society's efforts of social control. This resulted in members from less powerful groups being more heavily represented in prisons, and mental hospitals, which, in turn, led to their greater representation among the homeless, jobless, and those on welfare.

Subsequent conflict theorists raised issues such as how women (Belknap, 2001), GLBTQs (Comstock, 1991), and ethnic minorities (Tonry, 1995) were not represented in traditional theories of crime and deviance because their criminal behavior was different from that of white men and their victimization was ignored, minimized, or ridiculed by official agents of social control. An example of how the State used social control to keep the downtrodden down was noted by Michelle Alexander: many ethnic minorities, particularly Blacks, have been, for all intents and purposes, removed from participating in society because they are imprisoned at high rates, and lose many civil rights as a result (e.g., voting, gun ownership, cannot run for office, have trouble getting jobs) (Alexander, 2010). Theoretical discourse from this perspective, then, clearly illustrates the great mistrust sociologists of the time had for those in powerful positions.

For the last 300–400 years, sociological discourse on social control, crime, and deviance has branched out, providing numerous explanations for such behavior. Each theoretical exploration has undertaken a paradigmatic shift in the conceptualization of deviance and/or social control, or the methods used to study such. As such, perhaps the greatest recent contributions of sociologists to the study of social control and deviance are to use multifactor theories that pull a few of the most valid parts of several theories together, particularly those that examine both individual and society level factors. This also suggests that multimethod approaches will enhance our understanding of deviance. Using observation or ethnography as well as surveys or official data can all be combined to provide more complete accounts and descriptions of this important social phenomenon.

Social Democracy

Abstract

The term 'Social Democracy' has been used with a very wide variety of meanings since its introduction in France prior to the Revolutions of 1848. At various times and places, the social-democratic label has been adopted by revolutionary Marxist, democratic-socialist, center-left/liberal, and even conservative-authoritarian political parties and tendencies, usually with ties to blue-collar ('proletarian') labor unions. Most commonly, 'social democracy' is used in connection with the practices and ideas of parties that have belonged to the contemporary Socialist International or its preceding organization, the Second International. As parties calling themselves 'social-democratic' have grown steadily more moderate over time, gradually becoming less and less anticapitalist and antiliberal, usage of the term 'social democracy' has evolved in a similar fashion. In the year 2000 'social democracy' generally refers to a vague set of essentially liberal, center-left ideological and policy orientations, often associated with parties that belong to the Socialist International, that involve some combination of a relatively free-market-based capitalist economy, a fairly well developed welfare-state, a liberal-democratic ('polyarchical') political system, and a relatively internationalist approach to questions of foreign policy, security, and globalization.

The term 'social democracy' can refer either to a form of societal organization, an ideology, a set of public policies, a political party or group of parties, or a broad social and political movement centered on such parties and their allies within different sectors of society. The meaning of 'social democracy' has varied enormously since its original adoption by a small, vaguely-socialist group within the left wing of the French democratic-republican opposition prior to the Revolutions of 1848. At various times and places, the social-democratic label has been adopted by revolutionary Marxist, democratic-socialist, liberal/center-left, and even conservative-authoritarian political parties and tendencies, usually but not always with closer or more distant ties to blue-collar labor unions. Most commonly, the term 'social democracy' is used either in connection with political parties that have belonged to the contemporary Socialist International or its predecessor, the Second International of 1889–1914, or with reference to policies and ideologies close to such parties.

As parties calling themselves social-democratic have grown steadily more moderate over time, gradually becoming less and less anticapitalist and antiliberal, usage of the term 'social democracy' has evolved in a similar fashion. At the turn of the twenty-first century, 'social democracy' generally refers either to the programs and policies of the largely center-left political parties that belong to the Socialist International, or to a vague set of essentially liberal, center-left ideological and policy orientations that are often associated with these parties. While specific policies may vary, such center-left 'social-democratic' approaches share a commitment to a relatively free-market-based capitalist economy, a fairly developed welfare-state, a liberal-democratic ('polyarchic') political system, and a relatively internationalist approach to questions of foreign policy, security, and globalization. All over the world, parties and ideologies of this type are currently among the most important in the vast majority of countries with relatively competitive elections. The term 'social democracy' is rarely any longer used as a self-description by Marxist or other anticapitalist and antiliberal tendencies.

The History and Significance of Social Democracy

Ever since the Revolutions of 1848, which are generally considered to mark the birth of the social-democratic movement, the history of social democracy has been characterized by a profound ideological and tactical struggle between relatively radical, anticapitalist tendencies and relatively moderate, reformist orientations. In this dialectical contest, the radicals have generally adhered to some form of State socialism, usually of a Marxist (but anti-Leninist) variety, and/or some version of decentralized and radical-democratic cooperative socialism ('self-management,' 'economic democracy'); the comparatively moderate reformists, by contrast, have increasingly made their peace with multiclass ('catch-all') parliamentary politics, liberal ideology, and the capitalist system. Over the decades, this internal struggle has interacted with the often complex relationships of social-democratic movements with other political, social, and economic forces within particular societies to give rise to a wide variety of more or less 'socialist' ideological visions and public policies, often very effective and/or highly original, which have directly or indirectly exerted a tremendous influence on virtually all aspects of political, social, economic, and intellectual life in the modern world, particularly in countries with relatively capitalist economic systems and relatively liberal-democratic political systems. Although social-democratic movements and governments have frequently been frustrated in their reformist efforts by powerful domestic or international pressures, the resulting compromises and modifications have often marked significant new developments in the history of their respective countries, and of the world as a whole. Indeed, even when confined to the ranks of the political opposition in a particular country, social democrats have sometimes played a major role in bringing about

political, social, or economic reforms, by means of political pressure, foreign example, or intellectual influence.

Among the most important of these social-democratic contributions to the development of the 'welfare-capitalist' synthesis that has gradually come to dominate an increasing portion of the world since the 1880s, have been the following: (1) the striking (albeit gradual) democratization and humanization of political, social, and economic life; (2) the enormous growth and modernization of both the state and the economy, particularly in the realms of social policy, industrial policy, macroeconomic policy, industrial and labor relations (the much-celebrated 'democratic corporatism' of various Northern European countries, now largely defunct in a more market-oriented age), and recently also environmental policy; (3) the more or less successful promotion of social harmony and ideological consensus within previously much more polarized societies; and (4) strong support for international integration and world peace (although the temptation to join in nationalistic ventures, on the one hand, or in pacifistic crusades, on the other hand, has been a frequent source of tension within the social-democratic movement ever since its inception, most notably during the First World War).

Although self-styled 'social-democratic' parties and ideas have played a leading role in the history of an increasing number of countries around the world since 1880s, the concept of 'social democracy' is generally couched in terms based on the experience of Northern European Social Democratic, Socialist, and Labor parties (particularly those of Sweden and the other Scandinavian countries, as well as Germany, Austria, Great Britain, the Netherlands, and Belgium), because they have usually been the leading forces associated with the 'social-democratic' label, whether in terms of ideological and tactical development, policy-innovation, electoral support, governmental influence, or international prestige.

To the extent that world history since 1848 has been the story of the grand struggle between capitalism and socialism, social-democratic movements and ideas have often played a decisive role in finding a more or less successful middle-ground between the two (frequently under the slogan of some sort of 'Third Way' between unbridled capitalism and state-socialism), particularly in Sweden, Norway, and the other countries of Northern Europe. And to the extent that world history during the same period has been the story of the grand struggle between democracy and dictatorship, social-democratic movements and ideas have contributed greatly to both sides: on the one hand, social democracy spawned radical, antiliberal offshoots that quickly evolved into the rival totalitarian movements of communism and fascism during and after the First World War; on the other hand, social democrats have often played a decisive role in resisting and defeating these totalitarian movements, as well as other antidemocratic political, social, economic, and intellectual forces.

From the 1945 onwards social-democratic parties all over the world have grown steadily more dependent on the success of the welfare-capitalist social-market economy and the support of middle-class voters and relatively privileged elites in both the public and private sectors. This has been the result of two major interrelated processes: first, the continuation of these parties' aforementioned gradual movement toward the liberal center of the ideological spectrum; and second, the search for new bases of support and new reasons for existence under the impact of the gradual economic and cultural disappearance and disaffection of these parties' traditional blue-collar industrial ('proletarian') base. The first of these processes, that of increasing ideological moderation, has largely been due to the combination of mass prosperity, the rise of the welfare-state, profound political and social democratization, the failure of Marxist ideas and State socialist regimes ('real-existing socialism'), the spread of international peace and integration, American political and cultural hegemony, and the all-but-inevitable habituation of social-democratic elites to existing power-structures. The second process, namely the disappearance and disaffection of social democracy's old blue-collar base, has stemmed primarily from the combination of four interrelated developments that are associated with relentless economic and social modernization: first, much greater levels of social and economic mobility and opportunity, partly as a result of successful social-democratic policies; second, the accelerated disintegration and dissolution of inherited social and cultural solidarities and cleavages, including class-consciousness ('individualization,' 'desegregation,' 'depillarization'); third, the drastic weakening of inherited attitudes, beliefs, and values ('postmodernization,' the rise of 'postmaterialist' or 'left-libertarian' values), particularly among highly-educated elites; and fourth, the transition from a predominantly 'Fordist' socioeconomic system based on mass production in 'smokestack' industries, to an increasingly 'postindustrial' economy based on much more sophisticated technology, a much older, more highly-skilled, and more highly-educated labor-force, a burgeoning service sector, much more widespread share-ownership, much higher levels of flexibility in all areas of economic and social life, much greater concern for environmental protection, and much higher levels of international interdependence, integration, and homogenization ('globalization').

The Challenges Facing Social Democracy Today

In the twentieth century, social-democratic parties and elites increasingly staked their claim to rule less on utopian visions of 'socialism' than on their ability to manage and modernize the welfare-capitalist social-market economy more fairly, more humanely, more democratically, and, above all, more competently and more efficiently, than their rivals on right and left. Yet, although egalitarian and statist alternatives to free markets and a fairly rapacious capitalism were in the year 2000 weaker and more uncertain than ever before, challenges from the populist and often vehemently antiliberal and antimodern right, which since the 1980s has increasingly drawn the support of traditionally social-democratic (or communist or Christian Democratic) working-class voters, are often close at hand. Thus social democracy is faced with the difficult task of reconciling the interests and aspirations of an economically and culturally ever-more diverse potential constituency, a task which may prove extremely difficult once the worldwide economic boom at the turn of the twenty-first century dissipates. The danger, then, is that social democracy may become caught between the conflicting demands of relatively successful or privileged and

relatively unsuccessful or underprivileged sectors within increasingly unequal and *anomic* postindustrial societies, with the attendant risk that important groups within either or both sectors may gravitate toward antiliberal and antimodern movements on the left or, more likely, the right.

Editor's Note

Interest in social democracy among political scientists and sociologists has surged since the collapse of the Soviet Union, since on the world-historical stage, social democracy now represents the only realistic alternative to neoliberal capitalism. A work of great importance in this resurgent interest is Anthony Giddens, The Third Way: The Renewal of Social Democracy, first published in 1998 by Polity Press but reissued many times since. Numerous other recent works of interest might be mentioned; among the more commonly cited are: Waller et al., 2013; Meyer and Hinchman, 2007; Sassoon, 2014/1996.

Abstract

In social dilemmas, people face the dilemma to further their own interest or the collective interest. This article reviews the literature on social dilemmas, by discussing the main types of social dilemmas, and the main findings of social dilemma research. The focus is on understanding the psychological process, and the possibilities to solve social dilemmas.

Introduction

In social dilemmas, people face the dilemma to further their own interests or to further the collective interest, knowing that both interests collide. Consider, for example, the problem of maintaining collective resources. Resources such as energy, oil, and water, can be regarded as collective resources that should be consumed wisely. In such situations, group members may face the dilemma that, despite the collective interest to restrict consumption, it may be in their personal interest to consume excessively.

The term 'social dilemma' was coined by Dawes (1980) when he presented the first overview of (mostly psychological) research on this mixed-motive setting. When Dawes wrote his overview, the conflict between personal and collective interest had already caught the attention from scientists from diverse disciplines as economics, political science, and sociology. After his review, the attention increased even further. Inspired by game theory, and their particular research interests, scientists developed several distinct dilemma types that all model different aspects of social dilemmas.

Social Dilemma Types

Individuals against Individuals: The Prisoner's Dilemma

The prisoner's dilemma can be considered as the prototype, or blueprint, of social dilemma research. The prisoner's dilemma was designed by Melvin Dresher and Merrill Flood, two scientists at the RAND Corporation, but received its name by Albert W. Tucker (see for an overview on the origins of the prisoner's dilemma game Poundstone, 1992). The dilemma is often used as a metaphor of the cold war, where two blocks (east and west) are in conflict while sharing a common interest (preserve peace). In prisoner's dilemma games, individuals can choose between furthering their own outcome (i.e., the defect option) and furthering their collective interest (i.e., the cooperation option). The collective outcomes are higher if both players cooperate. However, if both players only try to maximize their own outcomes, this potential will not be reached. For these reasons, the dilemma can also be described as a clash of 'individual rationality' (maximize the own outcomes) and 'collective rationality' (maximize the collective outcomes).

Individuals in Groups: The Public Good Dilemma and the Common Resource Dilemma

Whereas the prisoner's dilemma only describes a dyadic setting, the conflict can meaningfully be extended to settings involving more persons (i.e., n-Person dilemmas). Indeed, this is the setting that most scientists have in mind when referring to the social dilemma.

Samuelson (1954) was one of the first to analyze the provision of public goods as a social dilemma in which the interests of individuals are at odds with the collective to which they belong. In its purest from, public goods are characterized by two properties: jointness of supply (i.e., consumption of one does not go at the expense of the consumption of others) and nonexcludability (i.e., nobody can be excluded from consumption). Because the first property will rarely be observed in real life, research has focused on the second property. The fact that one cannot be excluded from consumption – even if one does not contribute to the provision of the public good – raises the question of how one could expect anyone to contribute. This is, for example, problematic in the case of public television, where you can enjoy the fruits (i.e., watch TV) without contributing to its provision. Self-interest alone would lead to underprovision of public goods. In experimental research, this public good dilemma (also referred to as the 'Give-some dilemma'; Dawes, 1980) is generally modeled by endowing group members with money that can be contributed to provide a monetary for the group that is divided equally, regardless of one's own contribution. The bonus is often a linear function of the individual contributions (a linear/continuous public good; e.g., all contributions are multiplied by a factor 2), or a fixed monetary bonus that only becomes available if the combined contributions surpass a certain threshold (a step-level public good).

In 1968, Hardin wrote his seminal paper on 'The Tragedy of the Commons' in which he analyzed the problem of overpopulation from the perspective of social dilemmas. As a metaphor for population growth, he described a group of herdsmen who let their herds graze on a common pasture. The freedom of increasing one's own herd in the end leads to overgrazing and thus to (tragic) destruction of the commons. This analysis inspired researchers to develop the common resource dilemma as a research paradigm where group members can harvest from a common resource that may partially replenish, but will become depleted if overused. With the added feature of partial replenishment, the common

resource dilemma (also referred to as the 'Take-some dilemma'; Dawes, 1980) incorporates the distinction between short-term gains (excessive harvests) and long-term losses (depletion of the resource). The dilemma is generally seen as being at the heart of real-life problems of overconsumption (e.g., depletion of natural resources; overfishing; see also Ostrom, 1990).

Groups against Groups: Intergroup Competition

A special case emerges if two groups are in conflict. Such a dilemma could be described as a prisoner's dilemma between groups if one restricts one's analysis at the group level. If, however, one also incorporates the presence of individuals within groups, the situation becomes even more complex. It is this setting that Bornstein aimed to model when he designed the Intergroup Prisoner's dilemma game (Bornstein, 2003). In this dilemma, two groups are in competition, while the individuals within each group have to decide whether or not to cooperate. If the individual group members contribute to their group, the result can be fierce intergroup competition. In such a setting, the collective interest (i.e., the interest that all group members of both groups) may be served if individual group members decide *not* to cooperate within their group. A prototypical example of this type of dilemma is the setting where two nations are in conflict. Cooperation within each nation to fight the enemy may lead them to engage in war, with the collective threat of many casualties on both sides.

Groups within Groups: Nested Social Dilemmas

With nested dilemmas, the problem of cooperation is extended to an even higher level of complexity. In nested dilemmas, you can find subgroups, which are part of a superordinate group. In large organizations, for example, such a nested setting would refer to employees being members of departments that are situated (nested) within a large organization. The hierarchical and nested structure creates complex interdependencies such that cooperation *within* departments may lead to competition *between* departments that in the end may go at the expense of the organization at large (Wit and Kerr, 2002). Nested dilemmas are widespread. On a larger scale, we see countries nested within continents that together have a common interest to address environmental problems (like global warming or pollution of the oceans).

Groups after Groups: Intergenerational Dilemmas

Intergenerational dilemmas capture both the temporal and group dimension, by addressing the dilemma that people face when deciding whether or not to cooperate to benefit future generations. Global environmental change is one of the main problems that shows how our current state is affected by decisions of the generations that preceded us, and how the decisions we make can affect future generations. In addition to the temporal aspect, that may induce a stronger focus on current than on future outcomes, intergeneration dilemmas may suffer from the low level of identification with those who come after us. One of the main researchers on the psychology of intergeneration dilemmas is Kimberley Wade-Benzoni, who described the intergenerational dilemmas as a case of power asymmetry, where the parties who have control over the decision process (the present generation) are not the parties with most at stake (the future generations) (Wade-Benzoni, 2002).

Understanding Behavior in Social Dilemma Behavior: Main Observations and Explanations

Social dilemma research has identified the crucial factors that can promote or hinder cooperation. Interestingly, some of these promote cooperation in one type of dilemma and decrease cooperation in others.

Group Size

In general, group size has been found to decrease cooperation. This negative relation is mostly attributed to the fact that with increased group size, group members see their individual contributions are less essential. Increased group size leads to diffusion of responsibility, and reduced feelings of efficacy such that in large groups individuals may feel their contribution does not really add much to promote the interest of the group (Kerr, 1996).

Communication

Communication has generally been found to promote cooperation. A recent meta-analysis by Balliet (2010) showed that this is especially true for face-to-face communication. Several mechanisms may account for this positive relation. Communication may promote mutual promise making (and keeping) and enable people to commit themselves to promoting the group interest. Communication may also promote identification with the group. The meta-analysis also indicated that the positive effect of communication is stronger in larger groups, which may be explained by its potential to increase within-group identification. Of course, the group size does pose a boundary condition for effective communication, as in large groups (e.g., groups with 1000 individuals) communication may not be feasible. In this respect, it is telling that the meta-analysis on communication only included groups with group sizes lower than 10. Also note that sometimes communication may change this for the worse, for example, when in intergroup dilemmas within-groups communication increases within-group cooperation, but as a result increases intergroup competition (Goren and Bornstein, 2000).

Tacit Coordination

Even when opportunities for communication are limited, group members may sometimes tacitly coordinate their decisions. This means that even without communication, group members converge in the making of their decision (see for an overview De Kwaadsteniet and Van Dijk, 2012). For tacit coordination to work, group members need to have the feeling that the members in their group have a common understanding about the dilemma they face. Compared to continuous dilemmas, step-level dilemmas offer better prospects for tacit coordination because the threshold may serve as a focal point for coordination (e.g., Abele et al., 2010). An often used

coordination rule is the equality rule, which in step-level public good dilemma prescribes that all members contribute an equal share of the provision threshold. In asymmetric dilemmas (i.e., dilemmas in which group members occupy different positions, for example, when some group members are wealthier than others), alternative coordination rules may emerge. In public step-level dilemmas, for example, people rely on the proportionality rule if positions differ in terms of wealth (prescribing that people should contribute in proportion to their wealth). In addition, research showed that the preference for equality is stronger in the resource dilemma than in the public good dilemma (Van Dijk and Wilke, 1995).

Group Identity

Considering that in social dilemmas, individuals choose between furthering the own interest or the group interest, it makes sense to assume that identification with one's group increases cooperation. Such a positive link between identification and cooperation is indeed often observed (e.g., Kramer and Brewer, 1984). It should be noted that in some types of dilemmas, group identification may hinder the collective interest. In nested social dilemmas, identification with one's subgroup may reduce cooperation with the superordinate level (Wit and Kerr, 2002). In intergroup dilemmas high identification with the own group may result in competition with other groups. In this sense, effects of identification may resemble those of communication (which may not come as a surprise because communication may increase identification). In intergenerational dilemmas the paths of communication and identification need not align. While it is impossible (in the absence of a time machine) to communicate with future generations, we may identify with those who come after us (Wade-Benzoni, 2002) and thereby achieve intergenerational cooperation.

Reciprocity

In single-trial prisoner's dilemmas, a motivation to maximize one's own outcomes is served by the relative straightforward strategy to defect rather than cooperate. This may not hold in multitrial settings, however. Repeated interactions may make cooperation a more advantageous strategy by allowing for reciprocity (Gouldner, 1960), even in the absence of communication. The beneficial consequences of reciprocity were, for example, demonstrated in a tournament, organized by Robert Axelrod (Axelrod, 1980). He invited game theorists from economics, sociology, political science, and mathematics to send him their computerized strategies for a series of repeated prisoner dilemma games. All the submitted strategies, plus an added strategy of randomness, played 200 trials of a prisoner's dilemma against each other, the winner being the strategy that accumulated the highest outcomes. The glorious winner of the tournament was the Tit-For-Tat (TFT) strategy, submitted by Anatol Rapoport. TFT starts off with cooperation, but from then on reciprocates by choosing the same option as the opponent did in the previous trial (i.e., it responds to cooperation with cooperation and noncooperation with noncooperation). Whereas studies on multiple trials indeed show the emergence of mutual cooperation, one may also often observe a decline in cooperation toward the end of the trials (Murnighan and Roth, 1983). Reciprocity is even possible in intergenerational settings, when the current generation, for example, feels an obligation to respond cooperative to the cooperation of a previous generation (Wade-Benzoni, 2002).

Reciprocal strategies may promote mutual cooperation. In more recent years, building on evolutionary insights, the field has also identified reciprocal strategies other than 'just' direct reciprocity between pairs. Indirect reciprocity occurs when we cooperate with people because they cooperated with others. This mechanism works via reputation effects (Wedekind and Milinski, 2000): Building a positive reputation by cooperation may in the end bring you higher outcomes if others select you as the partner they want to cooperate with. Relatedly, cooperation has been interpreted as a costly signal that may attract others by sending the message that one is well-off *and* willing to help others (Van Vugt et al., 2007).

Environmental Uncertainty and Noise

Environmental uncertainty refers to uncertainty about features of the social dilemma, for example, about the exact size of the resource in a common resource dilemma, the threshold in a public good dilemma, or the group size dilemma (see for an overview Van Dijk et al., 2004). Cooperation usually drops under environmental uncertainty. The main explanations for this drop are that people may suffer from biased estimates (e.g., people harvest a lot because they overestimate the size of the resource in a resource dilemma), or opportunistically 'use' the uncertainty to justify their noncooperation (e.g., people justify their excessive harvests by arguing they thought the resource size would be large). In addition, uncertainty may reduce opportunities for tacit coordination (e.g., when the threshold becomes uncertainty) and lead to noncooperation by reducing people's sense of having a common understanding on what to do (De Kwaadsteniet and Van Dijk, 2012).

In more recent years, researchers have begun to study the effects of 'noise,' which basically refers to the difference between intentions and behavior, i.e., to when our intentions do not match with our behavior. Positive noise refers to unintentional cooperation; negative noise refers to unintentional noncooperation. Negative noise is the most severe threat to cooperation because people tend to respond negatively to noncooperation (due to the norm of reciprocity). In the case of negative noise, such a reaction of noncooperation would not be justified. One isolated instance of negative noise may, in 2-party interactions, trigger a chain of noncooperation if people adhere to a strict TFT-like strategy. The solution to this may be to adhere to a more lenient strategy, described as TFT + 1 (i.e., always be a little bit more cooperative than your partner; Van Lange et al., 2002).

Personality

People differ on many things, so it makes sense to assume that they may also differ in the weights they put on their own versus the collective interest. The different weighing of own and others' outcomes is central in research on social value orientations (Messick and McClintock, 1968). This research has identified three main personality types with regard to the

weighing of own and others' outcomes. Most people are competitive, individualistic, or cooperative (also referred to as prosocial); see for the most commonly used method to assess these personality types Van Lange et al. (1997). Individualists are primarily concerned about their own outcomes while competitors and prosocials do consider what happens to others. The competitor's interest is primarily in being better-off than others. Prosocials, are motivated to increase both the own and others' outcomes. A meta-analysis by Balliet et al. (2009) on 82 studies showed that these social value orientations strongly affect cooperation across different types of dilemmas, with prosocials consistently being more cooperative than competitors and individualists.

For dilemmas that include a temporal component, another personality difference seems of special relevance. People differ in their consideration of future consequences (Strathman et al., 1994). The general finding is that those with an eye on the future are more willing to cooperate, for example, by restricting their harvests in a common resource dilemmas to ensure future consumption (Joireman et al., 2009). It stands to reason that similar findings may be observed in intergenerational dilemmas, or other dilemmas with repeated encounters.

Solving Dilemmas

Understanding social dilemma behavior is one thing, solving social dilemmas is another. From the earliest studies on, the focus has been on how cooperation can be increased. Unfortunately, not all factors lend themselves to finding a solution. Personality differences should usually be seen as a given, and thus as a factor to be reckoned with, but not necessarily as key to solving dilemmas. Other factors may more readily be connected to solving social dilemmas. A distinction can be made between individual solutions and structural solutions (Messick and Brewer, 1983). Individual solutions more or less follow directly from the factors discussed above. Individual solutions may, for example, be to lower the group size, promote communication (either with or between groups), increase social identity or identification with the collective, and promote the feeling of having a common understanding (to promote tacit coordination).

Structural solutions are both more drastic and more promising in the sense that they address the heart of the problem: The outcomes structure of the dilemma. If social dilemmas are defined by their interdependence structure (which they are), it makes sense to change the interdependence structure. In their most extreme form, structural solutions may solve the dilemma by eliminating the (negative) interdependence between group members, and/or by making cooperation more attractive than noncooperation.

Leadership

The main conclusion in Hardin's (1968) seminal article on the Tragedy of the Commons was that to prevent the tragedy (of overpopulation) we need institutions that restrict individual freedom (as Hardin described it, we need "mutual coercion, mutually agreed upon"). One of the possible options that the early social dilemma research focused on was the installment of (autocratic) leadership. The installment of leadership (e.g., a central authority) to distribute a common resource over all group members not only removes the individual freedom to decide; it essentially restructures the social dilemma to a non-dilemmatic allocation setting. Such a solution can, of course, be very effective. But the solution to replace individual decision freedom by centralized leadership immediately raises the question of whether group members are prepared to freely give up their decisional freedom. Research shows that group members may (only) be willing to do so after high variance (i.e., when some members are a lot less cooperative than others), and collective failure (e.g., when the common resource becomes depleted) (e.g., Messick et al., 1983). It is interesting to see that preferences for leadership are also dependent on the dilemma structure. In general, the preference for leadership may be stronger in resource dilemmas than in public good dilemma. The call for leadership may be higher in the public good dilemma, however, after collective failure (i.e., if group members realize their individual contributions to the public good have been in vain; Van Dijk et al., 2003).

Sanctions

The most propagated solution to prevent noncooperation and to promote cooperation is to use sanctions. Sanctions can either take the form of penalties for noncooperation (negative sanctions), or rewards for cooperation (positive sanctions). Both rewards and punishments can be effective instruments (Balliet et al., 2011). Under some conditions, however, sanctions may countereffective (and promote noncooperation instead of cooperation). In particular, sanctions may undermine the intrinsic motivation to cooperate, by invoking a business frame. Rather than evaluating settings in ethical terms, sanctions may lead people to evaluate their decisions in terms of what they get out of it themselves (Tenbrunsel and Messick, 1999). If sanctions are (too) low, this may lead to a decrease of cooperation. Sanctions may also lower interpersonal trust, because the introduction of sanctioning system may signal to people that apparently others cannot be trusted to be internally motivated to promote the collective interest (why else would one need a sanctioning system?). Sanctions, may thereby create their own need, such that cooperation may collapse if a once installed sanctioning system is lifted (Mulder et al., 2006).

But even when sanctions are effective, one may wonder to what extent people are willing to install or use such sanctions. Here, the distinction between centralized sanctions and decentralized sanctions is important. Centralized sanctions are installed by one central authority; decentralized sanctions are sanctions that group members impose on each other (Balliet et al., 2011). The early studies on preferences for using sanctions primarily focused on centralized sanctions, and, for example, revealed that people are most likely to contribute to the installment of a sanctioning system if they both have the goal to further the collective outcome, *and* fear that others will not cooperate (Yamagishi, 1986). More recently, research has shifted toward the willingness to use decentralized sanctions. This shift was inspired by a study by Fehr and Gächter (2002). In a public goods setting, they assigned participants to 10 trials with and 10 trials without a sanctioning system. With

a sanctioning system, participants could reduce the outcomes of those who did not contribute. This punishment was not only costly to the punished person, but also to the punisher. The results showed the effectiveness of costly sanctions: Without a possibility to sanction, contributions to the public good were low, and even reduced over trials. With a possibility to sanction, contributions were high, and remained high. Apart from demonstrating the effectiveness of costly sanctioning, this study thus clearly revealed that people are willing to punish their noncooperative fellow group members, even if this means that they lower their own outcomes.

The above primarily highlights the instrumentality motive people may have to use sanctions (i.e., to promote cooperation). Whereas this may suggest that people primarily base their decisions on the (positive) expectations about sanction effects (e.g., I sanction to increase cooperation), emotions – and in particular anger – have been identified as a proximate mechanism (e.g., I punish because I am angry; e.g., Fehr and Gächter, 2002).

Trends in Social Dilemma Research

The previous overview illustrates the wide variety of issues that are covered by, and studied in, social dilemma research. We see the social dilemma logic being applied to diverse topics like intergroup conflict, public good provision, and management of scarce resources, to small-scale and large-scale settings, and to instant and temporal settings. The research on social dilemmas – being inspired by game theory – has traditionally made extensive use of experimental research with clearly defined paradigms. One of the trends has been to develop new paradigms to capture the complexities of social dilemmas we observe in real life (see, e.g., the intergroup dilemma, or the nested dilemma). Inspired by Nobel Prize winner Elinor Ostrom, we also witness more studies in the field. Another trend is that researchers from different disciplines more and more team up in their search for solutions to the social dilemma (see, e.g., the integration of insights from economics, social psychology, and evolutionary theory in the literature on sanctions). Combined, these trends will no doubt contribute to a better understanding of how we can manage the conflict between our own interests and the interests of the collective(s) to which we belong.

Social Dominance Orientation

Abstract

Social dominance orientation (SDO) is an individual's preference for group-based inequality and dominance versus equality and inclusion. SDO has multiple origins, including status, gender, socialization, and temperament and personality. SDO is a strong predictor of intergroup ideologies and behaviors, making it indispensable for studying intergroup relations.

Social dominance orientation (SDO) is an individual difference variable that explains sociopolitical attitudes, prejudice, and intergroup ideologies. As a part of social dominance theory (Sidanius and Pratto, 1999), SDO is an individual's preference for group-based inequality and dominance versus equality and inclusion (Pratto et al., 1994). A person's SDO compels them to adopt intergroup ideologies that either increase intergroup inequality (i.e., hierarchy-enhancing ideologies such as racism) or decrease intergroup inequality (i.e., hierarchy-attenuating ideologies such as feminism). Thus, it attempts to explain – at the psychological/individual level – why people adopt various intergroup attitudes or beliefs that can impact intergroup inequality at the societal level. As a general orientation toward intergroup relations, SDO is relevant across time and cultures (Lee et al., 2011; Pratto et al., 2014).

Origins of Social Dominance Orientation

SDO has multiple origins and causes (Kteily et al., 2011; Sidanius and Pratto, 1999). In the initial theorizing, it was proposed to have at least four causes: (1) group status, (2) socialization, (3) temperament, and (4) gender (Sidanius and Pratto, 1999). People who have high group status (e.g., European Americans, Pakeha in New Zealand, or Brahmins in India) have an interest in dominating surbordinate groups and maintaining their dominant social position, so they tend to be higher on SDO than people who have low group status (e.g., African Americans, Maori in New Zealand, or Dalits in India). Thus, group status is strongly related to SDO (Pratto and Stewart, 2012). Further, a wide variety of socialization processes reinforce which social groups should be at the top of the hierarchy and which social groups should be at the bottom. Media (news, television), educational experiences, social learning, and other factors communicate as to where social groups should be placed in a group-based social hierarchy, which can teach people to desire group-based inequality or equality. Also, some research suggests that different temperaments at birth give rise to differences in personality later in life (Sibley and Duckitt, 2008). These personality differences, such as openness to experience or agreeableness, can lead to different levels of SDO (Sibley and Duckitt, 2008). In a meta-analysis, SDO was related to agreeableness and also openness to experience (Sibley and Duckitt, 2008). Finally, men tend to be higher on SDO than women (i.e., the invariance hypothesis; Sidanius et al., 1994), so gender is an important predictor of SDO (Lee et al., 2011). Correlational research has established the relationships between SDO and these four factors, but greater research is needed to explore its origins.

In the most extensive theoretical treatment of the origins of SDO, Sibley and Duckitt (2008) argue that the development of a toughminded personality increases the development of a 'competitive jungle' worldview, where the world is seen as a dog-eat-dog world where people compete over material and symbolic resources. People's competitive jungle worldview then increases their desire for group-based dominance and inequality. Thus, SDO is proposed to be a function of personality traits and the development of a view of the world as competitive where every person must fight for themselves (Duckitt et al., 2002). Research examining the relationships among personality traits, cultural worldviews, and SDO provides evidence supporting this model (Duckitt et al., 2002).

In all, theory and research on SDO suggest that people's desire for intergroup inequality versus equality has multiple origins and causes, rooted in the development of personality and cultural worldviews.

Construct Validity of SDO

An important question since the theoretical development of SDO is 'What is social dominance orientation?' The construct validity of SDO has been questioned by social identity and system justification theorists (see Ho et al., 2012; Jost and Thompson, 2000; Kteily et al., 2011; Lee et al., 2011).

Since its inception, social identity theorists have criticized the construct of SDO (see Kteily et al., 2011; Lee et al., 2011), characterizing it as a mere reflection of social structure and intergroup attitudes. In contrast to this perspective, Kteily et al. (2011) argue that it is useful to view SDO as a cause and as an effect of intergroup attitudes. In a longitudinal study, participants' negative affect toward outgroups (e.g., Asians, Latinos, Blacks), ingroup friendship preference (e.g., a White person preferring to be friends with another White person versus a Black person), and SDO were measured in 1996 and once again in 2000. The results demonstrate that participants' initial levels of SDO strongly predicted outgroup affect and ingroup friendship preference 5 years later. In contrast, ingroup friendship preference in 1996 did not predict SDO 5 years later, and outgroup affect in 1996 predicted SDO weakly 5 years later (Kteily et al., 2011). This study provides evidence that SDO is a cause of intergroup attitudes and prejudice, but can also be

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24093-2

affected by prejudice, though weakly. The results from this study directly contradict the hypothesis that SDO is a mere reflection of social structure and intergroup attitudes and is instead a primary driver of intergroup attitudes.

A second issue raised by social identity theorists is that SDO is a mere proxy for ingroup identification (see Lee et al., 2011). Thus, one hypothesis derived from this perspective is that nations that are motivated to avoid uncertainty should display larger differences in SDO than nations that are not motivated to avoid uncertainty. It has long been demonstrated that uncertainty increases ingroup identification, so if SDO is a mere proxy for ingroup identification, then there should be larger group differences on SDO in nations high on uncertainty avoidance. However, in a meta-analysis investigating 206 samples from 1992 to 2009, nations that are motivated to avoid uncertainty have smaller differences between groups in SDO than nations that are not motivated to avoid uncertainty (Lee et al., 2011). Thus, the meta-analysis demonstrates the exact opposite pattern predicted by social identity theorists who claim that SDO is a proxy for ingroup identification. These results demonstrate that SDO is a unique predictor of intergroup attitudes and is not redundant with ingroup identification or other constructs derived from other theories of intergroup relations.

A third issue with the construct validity of SDO derives from system justification theorists, who characterize SDO as two factors, not one (Jost and Thompson, 2000; Ho et al., 2012). According to system justification theory, people are motivated to justify the self (ego justification), the group (group justification), and the systems in which they live (system justification). For subordinate group members (e.g., Blacks in the United States), there is a conflict between their motivation to see their groups positively and to see their systems positively because the system is oppressive. In order to manage this dissonance, subordinate group members rationalize and justify the system, viewing it positively. In line with this reasoning, Jost and Thompson (2000) argue that the SDO scale (a 16-item questionnaire designed to measure people's desire for group-based dominance versus equality) consists of two factors, viz., group-based dominance and opposition to equality. Group-based dominance is hypothesized to correspond to group justification, while opposition to equality is hypothesized to correspond to system justification. In correlational research, Jost and Thompson (2000) find that these two factors correlate more strongly for European Americans than for African Americans, and they differentially relate to psychological well-being, ethnocentrism, and support for social policies between the two different social groups. However, in the meta-analysis mentioned earlier, Lee et al. (2011) find results that contradict Jost and Thompson (2000). There were no differences between men and women on group-based dominance and opposition to equality, and the correlation between these two subscales was high, $r = 0.47$ (Lee et al., 2011). In ethnic/racial groups, there was a difference on opposition to equality ($r = 0.27$) but not on group-based dominance ($r = -0.08$), and these two subscales were correlated highly, $r = 0.83$ (Lee et al., 2011). System justification theory would predict a difference on group-based dominance and not on opposition to equality, so the findings in ethnic/racial groups also contradict the predictions of system justification theory. The results of this meta-analysis strongly suggest that SDO is a unified factor and does not consist of two subfactors.

Despite the results from this meta-analysis, some social dominance theorists have started to think of SDO in terms of two factors, providing a contradictory message in the literature. For example, Ho et al. (2012) argue that SDO consists of two factors, viz., SDO-D (dominance) and SDO-E (equality). Examining seven samples of participants, the authors find that SDO-D and SDO-E, though highly correlated with one another, differentially predict a series of criterion variables (Ho et al., 2012). For example, SDO-D relates to intergroup competition and aggression (e.g., immigrant persecution or nationalism), while SDO-E relates to subtle legitimizing myths and support for redistributive social policies (e.g., welfare policies and the Protestant work ethic). One explanation for this differential prediction is that there exist different psychological orientations underlying a general construct of SDO, as Ho et al. (2012) argue. However, another methodological explanation is that the actual items on the SDO have a semantic confound. For example, items used to measure SDO-E tend to be con-trait items, viz., items that measure being low on SDO (e.g., 'Group equality should be our ideal'; Pratto et al., 1994). This semantic confound between the SDO-D and SDO-E parts of the scale was addressed in a study using confirmatory factor analysis (Xin and Chi, 2010). In this analysis, the 16 items used to measure SDO were specified to load onto a single latent variable, SDO. A second latent variable was specified and consisted of the con-trait items. In a sample of 370 participants from the United States, Canada, and China, the results demonstrated support not only for a unified construct of SDO but also for a second factor controlling for the semantic confound. This analysis suggests that the SDO scale does measure a unified construct, but that the two supposed halves consist of a semantic confound. Further research is necessary to develop an SDO scale that does not have a semantic confound between the two halves of the scale.

Overall, there is strong evidence that SDO is a unified construct and is neither a proxy for ingroup identification nor a mere reflection of social structure and intergroup attitudes.

The Psychology of Low SDO

Although most of the research on SDO has explored the characteristics of people who are high on SDO (e.g., prejudiced, discriminatory, and punitive), very little research has explored the psychological characteristics of people who are low on SDO (Pratto et al., 2013). Toward this end, Pratto et al. (2014) conducted several studies to understand the psychology of people who desire equality and inclusion. In general, people who are low on SDO tend to be inclusive of social groups. These people tend to include more groups, people, and animals in their scope of moral concern (i.e., they care about the lives and well-being of all humans and nonhuman animals), be more empathic and express more empathy, support policies that include groups (e.g., extending marriage rights to gays and lesbians), and reject policies that exclude groups (e.g., more border patrols and fences at the U.S.–Mexico border). Further,

these people view their religious practices (e.g., fasting, praying) as a way to include other people in their faith, and they dislike group boundaries, segregation, competition, and rigid status differences. In all, people who are low on SDO are broadly inclusive.

Intergroup Ideologies and Intergroup Behavior

Social dominance orientation, as a general orientation toward intergroup relations, has tremendous predictive utility in understanding the commonality among a wide variety of intergroup ideologies and intergroup behaviors (Sidanius and Pratto, 1999). Intergroup ideologies are prescriptive beliefs that describe how people and institutions should behave (Pratto et al., 1999). Because ideologies correspond greatly to intergroup behavior, they are strong predictors of discrimination, collective action, and other intergroup behaviors (Pratto, 1999). However, ideologies are highly variable across cultures and across time (Lee et al., 2011). For example, the racism observed in contemporary U.S. society can be considered to be different from that observed in different periods of U.S. history (e.g., old-fashioned racism; Ho et al., 2012). Because of the cultural and historical variability in intergroup belief systems, SDO is an incredibly useful variable used to explain and to predict these vastly different belief systems (Lee et al., 2011). The SDO scale does not specify any particular groups and its content is temporally stable (i.e., groups exist across all historical periods), so SDO is a useful variable in understanding intergroup relations across time and cultures (Lee et al., 2011). Contrary to some researchers (e.g., Duckitt et al., 2002; Sibley and Duckitt, 2008), SDO is not an ideology because it is not historically or culturally specific. Instead, it explains the commonality of intergroup ideologies, which is that some ideologies increase intergroup inequality whereas other ideologies decrease inequality.

Social dominance orientation is useful in identifying an ideology's functional type (Sidanius and Pratto, 1999). Ideologies have two functional types: hierarchy-enhancing and hierarchy-attenuating. Hierarchy-enhancing ideologies (e.g., racism and sexism) promote intergroup behaviors that increase inequality between social groups (e.g., gender discrimination in the workplace or hate crimes). Hierarchy-attenuating ideologies (e.g., feminism and socialism) prescribe intergroup behaviors that decrease inequality between social groups (e.g., feminist activism or limiting commodity fetishism). People who are high on SDO tend to accept hierarchy-enhancing ideologies, and people who are low on it tend to accept hierarchy-attenuating ideologies (Pratto et al., 1994). For example, people who are high on SDO tend to provide more merit-based reasoning (e.g., Protestant work ethic) when deciding to allocate resources to different social groups, and people who are low on SDO tend to provide more need-based reasoning when allocating resources (Pratto et al., 1999). These ideologies provide people with the reasoning or justification to allocate resources to social groups and to engage in discrimination (Pratto et al., 1999). Also, SDO relates positively to racism, heterosexism, sexism, nationalism, and other hierarchy-enhancing ideologies, but it correlates negatively to support for progressive social policies (Lee et al., 2011).

Conclusion

Social dominance orientation is an important individual difference variable in the study of intergroup relations. SDO predicts a wide variety of ideologies and intergroup behaviors, is culturally and historically general, and offers unique insights into people's attitudes toward intergroup relations and social structure. In general, SDO is people's desire for group-based dominance and inequality versus inclusion and equality. It is determined from temperamental differences in infancy, socialization processes, group status, and gender, and the development of a competitive jungle worldview leads people to adopt a higher level of SDO. SDO is arguably a unified factor and a causal agent in driving intergroup attitudes and behaviors. People who are low on SDO tend to be broadly socially inclusive and desire social policies that include social groups in a society's scope of moral concern and justice. Finally, SDO is an incredibly powerful predictor of a wide variety of ideologies and intergroup behaviors, which makes it indispensable in understanding intergroup relations across time and cultures.

Abstract

Social ecology is a highly dynamic interdisciplinary research field rooted in both social science and natural science traditions. The common denominator of this research field is not so much a shared label but a shared paradigm. The core axioms in this paradigm are that human social and natural systems interact, coevolve over time, with causality pointing in both directions. Social ecology deals with energy and society, land use and food production, the metabolism of societies, and the environmental impacts of human activities. It offers a conceptual approach to society–nature coevolution that integrates historical and current development processes and future sustainability transitions.

Introduction

Social ecology constitutes a highly dynamic interdisciplinary research area with roots in both the social and natural sciences (see part 2). Whatever the discipline of origin, the common motive for moving into the direction of socioecological research has been to critically respond to decades of disciplinary differentiation and specialization that created a blind spot (Latour, 1991) detrimental to society's capability to properly understand and address its relation to the – seemingly increasingly strained – natural environment.

The common denominator of this research field is not so much a shared label – names extend, beyond social ecology, from human ecology, industrial ecology, and ecological economics to socioecological systems analysis – but a shared paradigm. The core axioms in this paradigm are that human social and natural systems interact, coevolve over time, and substantially influence each other, with causality pointing in both directions. What follows from this paradigm is a need to develop theoretical and epistemological concepts and research methodologies that can capture social and natural structures and processes in an integrated fashion. This challenge has been addressed in different ways and at different levels of depth and consistency across the various strands of social ecology.

In this article we first reconstruct some earlier academic roots of social–ecological thinking. Subsequently, we discuss key research traditions that deal with the biophysical features of human societies, such as energy, land use, and social metabolism. This is followed by a review of approaches to identifying environmental impacts of human activities. The fourth part is devoted to biohistory, and reviews theoretical and empirical efforts to analyze society–nature coevolution. Finally, we turn to issues of regulation and governance, with a particular focus on future sustainability transitions.

Academic Traditions Contributing to the Emergence of Social Ecology

The academic roots of social ecology can be traced back to the nineteenth century, partly because the social and natural sciences had not yet fallen into their respective epistemic boxes that made crossovers so difficult in the twentieth century. There are excellent reviews reconstructing such roots in the political economy of Adam Smith, David Ricardo, Karl Marx, and Thomas Malthus (Martinez-Alier, 1987; Sieferle, 1990; Fischer-Kowalski, 1998) illustrating the debates on the interrelations between population, land, food, technology, and economic development. While Smith, Ricardo, and Malthus remained focused on natural limitations to economic growth (in particular: land), Marx was the first to claim technological development (and thus: human ingenuity) as the key driver of economic growth, thus overcoming natural limitations.

Another influential field was geography. George Perkins Marsh's book *Man and Nature: or, Physical Geography as Modified by Human Action* (1864) inspired at least two major efforts to comprehensively account for human-induced changes in global ecology, namely the Princeton Conference on *Man's Role in Changing the Face of the Earth* (Thomas, 1956) and the 1987 conference at Clark University titled *The Earth as Transformed by Human Action* (Turner et al., 1990). In 1969 the German geographer Neef explicitly talked about the 'metabolism between society and nature' as a core problem of geography (Neef, 1969). Since then, geographers have played a major role in social ecology.

Cultural ecology, as brilliantly reviewed by Orlove (1980), must be regarded as another important predecessor of later social–ecological research. Similar to sociology, the beginnings of cultural anthropology (as in the works of Morgan, 1877) were marked by evolutionism, that is, the idea of universal historical progress from more 'natural,' barbarian social conditions to more advanced, civilized ones. Cultural anthropology subsequently splits into functionalist and culturalist strands. The functionalist strands retained a focus on the society–nature interface. Leslie White, one of the most prominent anthropologists of his generation and an early representative of the functionalist tradition, rekindled interest in energetics. For White, the vast differences in the types of extant societies could be described as social evolution propelled by energy and technology (White, 1943). In contrast, cultural anthropologist Julian Steward's 'method of cultural ecology' also paid attention to the quality, quantity, and distribution of resources within the environment, albeit with a different focus. This is exemplified by his comparative study 'Tappers and Trappers' (Murphy and Steward, 1955) which examines how two tribes that were traditionally reliant on subsistence hunting

and gathering (and some horticulture) completely change their ways of living as a result of changing their metabolism. The authors report an irreversible shift from a subsistence economy to dependence upon trade.

Despite some early calls for 'ecology of human' (Adams, 1935; Darling, 1956; Sears, 1953), biological ecology was reluctant to engage in human ecology prior to the environmental debate of the 1970s (Young, 1974). Moreover, when the first influential texts on human ecology appeared (e.g., Ehrlich and Ehrlich, 1970; Ehrlich et al., 1973), they adopted an approach that remained typical for much of the bioecological work until very recently: namely to view humans as a source of disturbance in ecosystems. Those resulted in a rather narrow concept of human agency which hampered interdisciplinary collaboration. The fact that ecologists tended to favor 'natural' ecosystems over 'human-dominated' ones as study objects may also have contributed to this bias. However, the most important factor was that many biological ecologists simply did not recognize the need to develop a more complex approach that conceptualizes socioeconomic systems as different from natural systems. This was further exacerbated by the dominance of neo-Malthusian ideas in bioecological approaches to human ecology (above all in the work of Paul Ehrlich) unpopular with social scientists. The revived environmental debates of the 1970s changed the situation: major international research programs were launched, including UNESCO's Man-and-the-Biosphere, or the International Human Dimensions Programme for Global Environmental Change, which stimulated and supported research across the 'great divide' (Snow, 1956) between the social and natural sciences.

History as a humanities discipline, in particular the tradition of the Annales School (e.g., Fernand Braudel), paved its own way toward social–ecological reasoning. Braudel viewed the history of the Mediterranean as an outcome of interaction between social and natural processes. Maurice Godelier formulates his core hypothesis in the introduction to *The Mental and the Material* as follows:

> Human beings have a history because they transform nature. It is indeed this capacity which defines them as human. Of all the forces which set them in movement and prompt them to invent new forms of society, the most profound is their ability to transform their relations with nature by transforming nature itself.
>
> Godelier, 1984, p. 1

This way of looking at history relates to the Marxist tradition but transcends it, instead taking ecological and/or coevolutionary directions. The classic reading of Marx leads to a discussion of changing 'modes of appropriation of nature' through the development of new means of production, namely technology. Godelier's reading stresses the fact that human appropriation of nature modifies nature and this modified nature in turn stimulates social change. Godelier thus deviates from mainstream social science approaches by viewing nature as historically variable, attributing societies' historical dynamics to a feedback process from nature. Since the 1970s, the field of environmental history has worked with this fundamental concept of mutuality of nature–society relations (Winiwarter and Knoll, 2007).

For sociology, some commentators see the so-called Chicago School of Human Ecology (Park, Burgess, Duncan) as an entry point to modern social ecology (Park, 1952; Duncan, 1959). This school used concepts and terminology from biological ecology such as hierarchy, competition, or succession to analyze urban development. However, the natural environment was largely reduced to spatial structures in the built environment. For example, Duncan's POET model (population, organization, environment, and technology) described social processes but did not refer to natural processes or conditions, with the exception of space (Beus, 1993). This said, some followers of the German human ecology tradition view this differently (cf Bruckmeier, 2004). Catton and Dunlap (1978) called for sociology to move beyond Durkheim's dictum that "a social fact can be explained only by another social fact" (cited in Beus, 1993, p. 94) and to abandon the 'human exceptionalism paradigm' in favor of an ecological paradigm in which the human species is one among other species on Earth, sharing their susceptibility to nature. This frequently cited appeal, nevertheless, did not immediately give rise to substantially new theoretical or empirical approaches. Almost a decade later, German sociologist Luhmann, who built upon the system-theoretical approach of biologists Maturana and Varela (1975), published an influential book (1986) on society's ability (or lack thereof) to adequately react to disturbances it initiates in its natural environment, even if these disturbances could prove to be detrimental to society in the long run. In the same year, Beck (1986) started to publish on 'risk society,' proposing that late modern society was characterized by the ways in which it creates and handles environmental risks and redistributes their consequences among its members. This starkly contrasts with traditional industrial society's preoccupation with its emancipation from natural forces and efforts to legitimately handle social inequalities. Jänicke (1988) and later Mol and Spaargaren (2000) opened a debate on 'ecological modernization.' They claimed that modern societies are capable of technological and organizational learning to mitigate or solve environmental problems. All these approaches, though, fall short of an epistemic turn toward a more symmetrical view of the social and the natural.

Society's Biophysical Structures

Energy and Society

The idea that control of energy matters for society, even determines the advancement of civilization, has a long tradition in social theory, prominently represented by Herbert Spencer. In his First Principles in 1862 societal progress and developmental gradients between societies are linked to energy consumption: The more energy a society is able to consume, the further advanced it is. Societal progress is based on energy surplus because it enables social growth and differentiation and frees up time for cultural activities beyond work to meet basic vital needs. Cottrell (1955/2009), on the other hand, offered a more nuanced analysis of the relevance of the sources and amounts of available energy for social processes that steered clear of the more narrow energetic evolutionism embraced by Spencer and Morgan. Similarly, physicist Vaclav Smil published periodic compendia on *Energy in the Biosphere*

and Civilization (1991) up to *Energy in Nature and Society* (2008) that compiled encyclopedic knowledge on how energy matters. Another physicist, Robert Ayres, has presented convincing theoretical and empirical evidence that the expenditure of useful work (i.e., exergy) was, and is key to economic growth (Ayres and Warr, 2005). The historian Rolf Peter Sieferle (1982, 2001b) analyzed the rise of the United Kingdom into industrialization and political hegemony as an outcome of its 'subterranean forest,' i.e., its use of coal that gave it access to significantly more energy than if the United Kingdom had had all its territory covered with forest and burned it for energetic use. Currently, the issue of reducing fossil fuel consumption to both address 'peak oil' (and peak fossil fuels more generally, cf Murphy, 2012) and avoid dangerous climate change and its potential consequences for economies and societies, is stimulating much research on the potential consequences of changing society's energy base and possibly reducing the energy intensity of social processes altogether.

Land Use and Food Production

That societies extend over territories and restructure them for social purposes, with severe consequences for social as well as natural processes, is not a new issue among social scientists. However, it has regained considerable momentum of late. Ester Boserup (1965, 1981), both in her continuation and her critique of Neo-Malthusianism, was simultaneously at odds with the development policies of her time by (empirically) demonstrating social learning processes in response to population growth and food scarcity. She was able to show that traditional agriculture had found ways to feed an expanding population by intensifying land use (and not only, as in the Malthusian paradigm, by extending agricultural area). Land-use intensity is an essential aspect of the human use of terrestrial ecosystems. In the course of history, the intensification of land use allowed to overcome Malthusian traps and support population growth as well as improving supply of food and other products dependent on photosynthesis. It helped to achieve increases in agricultural production without requiring proportional increases in the area of agricultural land. On the contrary, intensification ensured that most industrialized countries increased their agricultural output in spite of shrinking agricultural areas in the last decades, if not centuries. In the industrial part of the world, we find reforestation instead of long-term deforestation (although this is partly because of deforestation and 'land grabs' in developing countries). On the other hand, increasing land-use intensity has often been associated with detrimental effects of land use on ecosystem functioning, such as soil degradation, groundwater and air pollution, and biodiversity loss. Such processes have had negative effects on the ability of ecosystems to sustain vital ecosystem services, thereby potentially jeopardizing human well-being in the long run. Under conditions of traditional agriculture, which largely prevailed worldwide until the 1960s, increased food output per unit area was achieved through increased investment of human labor (Boserup, 1981). This, in turn, incentivized high fertility to provide the necessary labor power, thereby contributing to population growth. When fossil fuels use facilitated the industrialization of agriculture (mineral fertilization, pesticides, tractors), this started to change (cf. Fischer-Kowalski et al. 2014a), with agriculture turning from a supplier of energy to a consumer (Pimentel et al., 1973). Emerging toxicological hazards linked to agriculture such as those documented in Rachel Carson's seminal book *Silent Spring* (1962) ran the risk of poisoning the entire food chain. More recently, the debate has revolved more around the risks of genetic engineering (see for example the Nature Special Feature, 2013). Importantly, the issue of land use and land cover change has mobilized a large research community (most recently, the international program on 'Future Earth,' http://www.icsu.org/future-earth) working on food security, diets, carbon emissions, biodiversity losses, climate and habitat change through broad interdisciplinary cooperation.

Social Metabolism/Industrial Ecology

Ecological Economics

While Marx had already recognized the centrality of social metabolism with nature for human labor (Marx, 1867/2010), these considerations resurfaced in Ayres' and Kneese's work in the second half of the twentieth century. They claimed that the common failure of economics results from viewing production and consumption in ways that are at variance with the fundamental law of the conservation of mass (Ayres and Kneese, 1969, p. 283). They argue that uncompensated externalities such as pollution and waste are inevitable unless the following three conditions are met: (1) all inputs into the production process are fully converted into outputs, with no unwanted residuals along the way; (2) all final outputs (commodities) are completely used up through consumption; and (3) property rights guarantee that all relevant environmental attributes are in private ownership and that these rights are exchanged in competitive markets. Given that these three conditions are never fully met in practice, environmental policies targeting wastes and emissions must take into account the full cycle of industrial metabolism to succeed (Ayres and Simonis, 1994).

The Viennese School of Social Ecology has introduced a paradigm for social–ecological research by placing social metabolism within a wider picture of society–nature interaction (**Figure 1**).

This model depicts social metabolism as one of the key links between society's biophysical structures (defined as human population, livestock population, and physical infrastructures,

Figure 1 Society–nature interaction and the role of social metabolism. Source: Elaborated after Fischer-Kowalski, M., Haberl, H., 2007. Socioecological Transitions and Global Change: Trajectories of Social Metabolism and Land Use. Edward Elgar, Cheltenham, UK; Northhampton, USA, p. 13 © Institute of Social Ecology (SEC).

including technical equipment) and the natural environment. In order to reproduce its biophysical stocks, society needs continuous flows of energy and materials. At the same time, it expands labor to intervene in nature and modify it according to society's needs (e.g., agriculture, construction activities). Society's biophysical structures are shaped by events that happen in nature. Through culture and communication, society represents these events, interpreting them as rewards for people's efforts (e.g., a large harvest), as catastrophes (e.g., floods), or possibly as irrelevant. In the other direction, there is a cultural program that translates into action. An interesting feature distinct to this model is the overlap between the natural and the cultural–symbolic realms: elements are neither exclusively natural nor purely cultural, but are governed by both natural and cultural factors. In other words, society is a hybrid of the two realms (see also Boyden, 1992). Recent similar conceptualizations used by Liu et al. (2007), who talk about the complexity of coupled human and natural systems, and Becker (2013), who emphasizes the importance of hybrid structures, continue and expand on this paradigmatic tradition.

By conceptually linking metabolic flows with biophysical stocks in this way, it is possible to define boundaries for social systems (vis-à-vis both their natural environment and each other) and to create a consistent metric for material and energy flows for social systems on various scales (local communities, firms, cities, or nation-state). For example, national material flow accounting has become a regular part of public statistics in Japan, the European Union, and elsewhere (Fischer-Kowalski et al., 2011). It provides reasonably reliable annual accounts of natural resource use in physical terms and allows for their comparison across time and with economic accounts (**Figure 2**). On the global scale, adding up all the extraction of natural resources that occurs during a year produces useful figures while, at the same time, avoiding the complexities of international trade networks that distribute these resources around the globe (**Figure 3**).

Figure 2 illustrates an eightfold increase in resource extraction during the twentieth century across the following areas: Biomass, construction minerals, fossil energy carriers, and metals (including industrial minerals). While societies at the beginning of the century reproduced themselves mainly through biomass inputs (i.e., food for humans and animals, firewood), they increasingly turned toward the so-called nonrenewable resources such as fossil fuels and ores (Krausmann et al., 2009). Moreover, biophysical stocks clearly increased between 1900 and 2000, with the human population increasing fivefold. In addition to this substantial population growth, metabolic rate, that is, resource use per person also doubled, from less than 5 tons per person per year to almost 10 tons. This was complemented by an even greater increase in world GDP (at constant prices) and average income per person. This apparent 'decoupling' of resource use and income is mainly due to technological progress that facilitates producing more value with less input, which also makes products cheaper. However, this also feeds into further growth of resource consumption: an hour's work can buy more products.

For nation-states, there is a rich literature comparing resource requirements (e.g., Weisz et al., 2006 for the European Union), resource efficiencies (e.g., Schandl and West, 2010 for Asia and the Pacific), trade patterns (e.g., Dittrich and Bringezu, 2010), and growth in biophysical stocks across countries. On the other end of the metabolic process, there is particular interest in researching greenhouse gas emissions (that can be calculated from fossil fuel use, livestock numbers, and steel and cement production) that either occur directly within countries or result from international trading. Naturally, these emissions are highly relevant for climate policies.

Interest in the metabolism of cities has surged of late, with city planning being identified as an important means to reduce resource consumption while maintaining welfare levels. Substantial amounts of energy for heat and transportation, construction materials, and land can be saved by appropriate spatial structures (Kennedy et al., 2007; Weisz and Steinberger, 2010).

Figure 2 Global social metabolism during the twentieth century. Source: UNEP, 2011. Decoupling Resource Use and Environmental Impacts from Economic Growth. United Nations Environmental Programme, Paris.

Figure 3 Interrelation between the human development index and the ecological footprint.

A somewhat different metabolic approach is chosen by Giampietro et al. (2012). Their "Multi-Scale Integrated Analysis of Societal and Ecological Metabolism" (MuSIASEM) systematically relates human labor, exosomatic energy use, and economic output to describe the metabolic pattern of various types of social systems (from households to farms to national economies, stratified into sectors). This approach builds on Georgescu-Roegen's (1971) foundational work on 'bioeconomics,' which influenced the emergence of ecological economics.

Identifying Environmental Impacts of Human Activities

In the 1970s, the so-called IPAT equation was developed from a debate about the relative importance of population growth on the one hand, growth in affluence on the other, in determining human impacts upon the environment (Ehrlich and Holdren, 1971; Chertow, 2001). IPAT is the lettering of the following formula:

$$I = P * A * T$$

where I stands for (environmental) Impact, P for Population, A for Affluence, and T for Technology. This formula has been repeatedly applied to estimate various environmental impacts such as land and resource use, pollution, CO_2 emissions, or the ecological footprint (EF) (see below). More statistically elaborate applications use regression analysis to determine the relative weight of the components and to calculate both nonlinearities and interactions (e.g., Dietz et al., 2007). The hope attached to this equation, that technological improvements would neutralize at least some of the ecological damaging effects of population growth and increasing affluence, is not strongly substantiated. In some cases the opposite occurred. For example, Schandl and West (2012) found that the impact of increasing affluence on CO_2 emissions in Asian and Pacific countries was further exacerbated by technology changes. This seems plausible given that economic growth in developing countries typically implies a shift toward using fossil fuels. For a long-term IPAT analysis with similar outcomes see Fischer-Kowalski et al. 2014b.

Another widely used approach to describing human environmental impact is the so-called EF. In 1996, Wackernagel and Rees published the book *Our Ecological Footprint: Reducing Human Impact on the Earth*. Per capita EF, or EF analysis, is a means of comparing consumption and lifestyles, and checking this against nature's ability to provide for this consumption. It does this by assessing the biologically productive land and marine areas required to produce the resources a population consumes and to absorb the corresponding waste using prevailing technology. The EF is expressed in 'global hectares.' Despite several modifications, this indicator has been subject to considerable methodological criticism (cf Gaube et al., 2013), including how different land productivities are taken into account (Haberl et al., 2004), or how trade can be integrated into the picture (Grazi et al., 2007).

This said, it remains one of the most powerful tools for communicating the human impact on the environment. Moreover, it can inform policy by examining to what extent a nation uses more (or less) than is available within its territory, or whether a nation's lifestyle would be replicable worldwide. The footprint can also be a useful tool for educating people about carrying capacity and overconsumption, with the aim of changing behavior. EFs may be used to argue that many current lifestyles are not sustainable. Global EF comparisons also clearly show the deep inequalities in resource use on this planet at the beginning of the twenty-first century.

From a social science perspective, these indicators and analyses of environmental impact cannot adequately capture the complexity on the social system side of the metabolic process and usually lack a coevolutionary perspective. While

they recognize that humans exploit nature, they do not include how nature hits back or what adjustments human societies (are forced to) make in response to environmental problems.

The so-called DPSIR model – D = Drivers, P = (environmental) Pressures, S = States (of the environment), I = (environmental) Impacts, and R = (policy) Responses – as used by the OECD and the European Environmental Agency attempts to address this gap. It assumes a causal chain whereby social causes ('drivers') exert pressures upon the environment that trigger changes, with society subsequently responding to those changes with (presumably ameliorating) policies. Still, while the DPSIR model focuses more on social processes than its predecessors, it does so in a rather narrow way (Stanners et al., 2007).

Biohistory and Society–Nature Coevolution

There is a long tradition in the social and historical sciences to distinguish between qualitatively different forms of societal organization, subsistence or production, or to identify diverse stages of civilization or development. The distinctions drawn, and the criteria upon which these are based, vary considerably but rarely refer to society–environment relations or environmental consequences of human activity.

It has been the special achievement of Rolf Peter Sieferle (1997) to regard different forms of societal organization not only as socially or socioeconomically distinct entities but to systematize them according to their socioecological patterns. This implied considering both social organization (in the widest sense of the word) and concomitant changes in the environment. Key to Sieferle's distinctions is society's key source of energy and its dominant conversion technology for energy production. He distinguishes between the hunting and gathering mode, the agrarian mode (with some subdivisions), and the industrial mode. The energy system of hunters and gatherers is 'passive solar energy utilization.' They live on the products of recent photosynthesis (plants and animals for their food, firewood for heat). That they use fire to cook (rather than grill) their food widens the specter of edibles – but still, only a very small fraction of their environment qualifies as food whose collection requires mobility, both on an everyday basis and seasonally, allowing only for very low population densities. In contrast, the agrarian mode is based upon 'active solar energy utilization,' implying that certain areas are cleared of their natural vegetation and that solar energy on these areas is instead monopolized to grow human food plants. This leads to extensive deforestation of the Earth (and the enrichment of the atmosphere with the CO_2 that previously had been stored in trees and soils), a sedentary way of life as well as a large human labor burden (despite technological improvements to increase yields, Boserup, 1965, 1981). Resulting changes in lifestyle and nutrition allow for higher fertility while the large labor burden motivates having children to share the labor. The resulting growth in population creates high population densities and an expansion of the agrarian mode across the world. Control of territory, tools, livestock, and stored reserves is essential, and frequent territorial conflicts lead to the emergence of specialized classes of people to defend and attack territories, social hierarchies to control them, and urban centers that offer protection and opportunities for trading. In many parts of the world, these agrarian systems developed into major empires and civilizations that emerged, flourished, and in some cases collapsed again (Diamond, 2005; Tainter, 1988).

In the sixteenth century, a new fossil fuel-based energy system started to emerge, supplying society with an unprecedented amount of energy. In the United Kingdom, the use of coal instead of increasingly scarce firewood initiated urban growth and industrial manufacturing. Textile production for export became very profitable and sheep gradually crowded out farmers growing food. The invention of the steam engine finally triggered what is now known as the industrial revolution, which caused large-scale ecological and social transformations. Industrialization continues today, spreading from the core industrialized countries (comprising about 20% of the world population) to the much larger rest of the world at an accelerating speed (Fischer-Kowalski and Haberl, 2007). It remains to be seen whether the exhaustion of fossil fuels, a detrimental transformation of the Earth's climate system, or politically guided change will bring an end to this energy regime. In any case, it is likely that the fossil fuel era will have lasted for a much shorter period of time than the two previous regimes.

Overall, the main appeal of Sieferle's classification is that it sheds light on different functional problems societies face when trying to establish and maintain themselves under specific environmental conditions and the associated evolutionary advantages and drawbacks. Moreover, Sieferle's approach also provides some clues about the possible direction of change. More recently, a new research area has emerged from ecological observations of long-term processes across a global network of local and regional habitats (also called Long-term ecological research sites). In recent times, this research has been extended to also focus on social processes, culminating in the LTSER network (long-term socioecological research, see Singh et al., 2013).

Regulation, Governance and Sustainability Transitions

Good governance of the commons (or lack thereof) is a long-standing socioecological theme. Departing from existing models of collective action, Elinor Ostrom's book, *Governing the Commons* (1990) stimulated a rich strand of research in the area of new institutional economics, which culminated in her winning the Nobel Memorial Prize in Economic Sciences in 2009. The focus of her research was on how people manage common-pool resources such as land and water to maintain long-term sustainable resource yields. Her field studies focused on the management of pastures and irrigation networks by local people and documented how societies have developed diverse institutional arrangements for managing natural resources and avoiding ecosystem collapse. Ostrom (1996) identified a number of 'design principles' of stable local common-pool resource management including:

- Clearly defined boundaries (effective exclusion of external un-entitled parties);
- Collective-choice arrangements that allow most resource appropriators to participate in the decision-making process;
- Effective monitoring by agents who are part of, or accountable to the appropriators;
- A scale of graduated sanctions for resource appropriators who violate community rules and mechanisms of conflict resolution that are cheap and easy to access.

In her later work, these principles have expanded to include a number of additional variables believed to affect the success of systems of self-organization and self-governance, including effective communication, internal trust, and reciprocity.

Ostrom and her many coresearchers developed a comprehensive 'Social–Ecological Systems framework,' within which much of the still-evolving theory of common-pool resources and collective self-governance is now located (Ostrom, 2009). A strong research community that relates to these approaches is the Resilience Alliance. This network of institutions and people publishes the influential open-access journal *Ecology and Society* and defines socioecological systems as

> a multi-scale pattern of resource use around which humans have organized themselves in a particular social structure (distribution of people, resource management, consumption patterns, and associated norms and rules) …Hence, the main aim of resilience management and governance is to keep the system within a particular configuration of states (system 'regime') that will continue to deliver desired ecosystem goods and services and prevent the system from moving into an un-desirable regime from which it is either difficult or impossible to recover, or, to move from a less desirable to a more desirable regime.
> http://www.resalliance.org/index.php/key_concepts

The Frankfurt approach to social ecology deploys the core concept of 'societal nature relations' (*gesellschaftliche Naturverhältnisse*), focusing on the *relations* between society and nature in terms of the various societal *regulations* that define them. Operationally, this approach focuses on *basic* societal nature relations such as freshwater or food supply that are indispensable for meeting basic human needs and for individual and societal reproduction and development. The link to the concept of human needs turns societal nature relations into an irreducibly *normative* concept: the basic societal nature relations ought to be *regulated* in such a way that *all* human are able to meet their basic needs (Becker et al., 2011, p. 79). The Frankfurt approach defines as its 'epistemic object' the 'crisis of society–nature relations' (Becker and Jahn, 2006, p. 19). This definition is highly normative in that presupposes a crisis, that is, a dramatic deviation of the 'is'- from the 'ought'-state of societal nature relations. The purpose of social ecology is thus to generate the knowledge to understand and react to this crisis, with a view to reaching the desired 'ought'-state of societal nature relations. The core research question of social ecology is thus: "How can crisis-ridden societal nature relations be perceived, understood and actively shaped?" (Becker and Jahn, 2006, p. 12). In the 1990s, the German Government established an interdisciplinary social–ecological research program that reinforced this orientation toward basic needs, demanding strong involvement of stakeholders and strengthening the policy relevance of socioecological research in Germany over many years.

The Dutch societal transitions management school adopts a similar approach to managing human-environment systems. In contrast to the resilience alliance tradition, the Dutch school focuses more on interactions between technical and social systems. The core concern are 'wicked' problems in social system functioning that cannot be solved through conventional means but that require a systemic transition. A social–ecological transition is a transition between two dynamic equilibria, that is, a shift from one more-or-less stable state to another. The typical model of a transition is the S-curve, which allows for the distinction of discrete phases: a 'predevelopment phase' in which some processes start to deviate from the dominant pattern; the 'takeoff phase' involving a departure from the original equilibrium; an 'acceleration phase,' where change accelerates in a nonincremental, disruptive, and potentially chaotic manner; and a 'stabilization phase,' where the rate of change is declining and a new dynamic equilibrium is approached (Rotmans et al., 2001, p. 1). The nature of transitional dynamics is described as a generic sequence of mechanisms that result in irreversible changes in the system. 'Niches,' that is, individual technologies, practices, and actors outside or peripheral to the existing regime function as potential drivers of radical innovation (Geels, 2005). Niches emerge and cluster, and by empowering a niche cluster, a niche regime unfolds. This niche regime may then become more powerful, finally dominating and replacing the incumbent regime. Underlying mechanisms are variation and selection, adaptation, emergence, clustering, empowerment, transformation, decay, and building up. Transition management draws together a number of front-runners in a protected environment or arena. To effectively create a new regime, agents need to be at a certain distance from the incumbent regime. However, the continuous link with the regime is also important, requiring buy-in from regime agents that are open to change. The methodological concept of transition management frequently draws on this 'Multi-Level Perspective' on an evolutionary dynamics between a micro (niche), meso (regime), and macro level. Transition management was taken up by the Global Energy Assessment (GEA, 2012) and UNEP for framing its new modeling approach (UNEP, 2013).

To conclude, many of the social ecology approaches reviewed in this article are known and used by natural scientists interested in sustainability questions. However, they appear to be less popular among social scientists who follow more traditional disciplinary pathways. This said, social ecological concepts and methodologies enjoy increasing popularity within the rapidly expanding social–scientific sustainability research community (cf Rau and Fahy, 2013). Greater involvement by social scientists in interdisciplinary debates about humanities' long-term future on Earth would help to further progress a paradigmatic shift toward social–ecological thinking, policy, and practice.

Abstract

This article presents social ecology as used in the social and behavioral sciences, with special emphasis on the research conducted by the Chicago School of Sociology. By sketching the central concepts from plant and animal ecology, the author shows how these concepts were transferred to the study of human communities. Additionally, it is shown how social ecology altered the methods used in the social and behavioral sciences. In a final section, the reasons why the approach lost influence are given and personal and thematic successors of the approach presented.

Social ecology describes the conceptual adaptation of plant and animal ecology to the analysis of human communities within the social and behavioral sciences. The approach is also known as human ecology and was particularly used in the early twentieth century to explain the change of societies within their physical environment over time. Its central topic of research was the social and spatial structure of industrial societies, mainly in the context of urbanization. Research with an ecological focus was prominently carried out by sociologists at the University of Chicago from the 1920s to 1930s onward, later known as Chicago School of Sociology. The sociological research using ecological concepts will therefore be in this article's focus.

Origins of Social Ecology

Social ecology as field in the social and behavioral sciences roots in the times when disciplines like sociology, psychology, demography, or economics were still quite young scientific disciplines. In search for theoretical concepts and methodological frameworks, researchers started to use the concepts of ecology for the study of human communities in the late nineteenth and early twentieth centuries. In doing so, the researchers transferred the main concepts and explanatory structures of the (biological) theory of evolution to the changes of human communities. The community as basic unit of analysis in plant and animal ecology was then also used as unit of analysis in the social and behavioral sciences. The scientific analysis of human communities was the scope of the human ecology of that time. The general assumption was that both human behavior and the institutional order of a community were relative to time and space, i.e., that the development of a community had a spatial dimension and processual character. The development of human communities in general and differences between various human communities were explained on the basis of ecological concepts.

Next to the concept of community, concepts like dominance, succession, cooperation, competition, natural areas, and centralization/decentralization were adopted from the theory of evolution. They as well were ecological concepts now used to explain processes of human development and the structure of societies. Roderick McKenzie therefore defines human ecology as the "study of the spatial and temporal relations of human beings as affected by selective, distributive and accommodative forces of the environment" (McKenzie, 1925: p. 63f.).

Ecological Concepts and Their Transfer to Social and Behavioral Sciences

When transferring theoretical concepts from plant and animal ecology to human ecology, the life course of a plant or an animal was used as analogy to describe the development of a human community. The German ecologist Ernst Haeckel described the life course of an individual as consisting of three phases (Haeckel, 1866: pp. 76–81): youth/adolescence, adulthood/maturity, and age/decline. In the first phase, the young organism grows until maturity is reached. In this second phase, the organism is highly differentiated. In the following third phase, decline begins that ultimately leads to the death of the organism.

Translating these phases to human communities was used as a tool to explain the communities' development both in temporal and in spatial terms: during a first phase of development, a community extends in growth, both in numbers and in spatial terms, until reaching a point of equilibrium that corresponds to the human phase of maturity. In this second phase of development, the individuals in the community live in a defined area. After the equilibrium is exceeded, the community tends to decline in growth, again both in terms of numbers and its spatial spread.

The process of growth–stability–decline affects the forces at work in the community: during the first phase, the species of the community stand in competition to each other, each striving for dominance. In the second phase, the equilibrium is accompanied by an established social order where the species cooperate rather than compete in order to survive in the best way possible. In addition, the principle of dominance is at work: a fixed power relation is established that implies a social order in which one group dominates the others. During the third and last phase, the phase of decline, competition increases as the equilibrium is disturbed and social forces are released. Social disorder and economic destabilization are the results.

Main Ecological Concepts Used in the Social and Behavioral Sciences

Communities

The main topic of ecology is the analysis of communities – this is true for plant and animal ecology and for human ecology. In the nineteenth century, ecologists studied plant and animal communities to understand the "complex relations of all animals and plants to each other" (Darwin, 1937: p. 79), also called the "web of life" (Thomson, 1914: p. 263). The basic finding was that the species in a community, understood as the community's units, each have a specific role and are interrelated to the other species in the environment.

This concept of a community whose members share the same physical environment and interact in a specific way was then transferred to human communities (see, e.g., Park, 1915; McKenzie, 1925). Robert Park, one of the representatives of social ecology in sociology and a central figure of the Chicago School of Sociology, differentiates between biotic and cultural communities to describe the different elements of human communities. According to him, human societies vary from plant and animal societies in one respect: on top of an ecological order that builds the fundament of a human community, there exist three further orders: an economic, a political, and a moral order (Park, 1936: p. 14). All three account for the existence of what Park calls "cultural community" (Park, 1936: p. 9), and are the distinctive feature of human societies.

This understanding of human societies as comprising two forms of sociality relates to Ferdinand Tönnies (1991[1887]) differentiation of 'Gemeinschaft' and 'Gesellschaft'. The biotic community, a "Gemeinschaft", forms the basis for "the cultural superstructure" (Park, 1936: p. 13), i.e., the cultural community or 'Gesellschaft', in which complex forms of social control, moral norms, and institutions are responsible for stability, but also social change. By including the ecological concepts of competition and cooperation as characterizing forms of interaction in his model, Park stresses the fact that the human biotic community is, analogous to plant and animal communities, characterized by competition, whereas the cultural community is based on "custom and consensus" (Park, 1936: p. 13). With these differentiations, Park formulates the peculiarities of a decidedly 'human' ecology in contrast to 'plant/animal' ecology.

Natural Areas

By conceptualizing the physical environment of the communities as constitutive feature of their formation, Park, like his colleagues, integrates another important element of ecological theory, the role of the habitat, in the concept of the biotic and cultural communities. The development of communities leads to the formation of rather homogeneous sociospatial areas, in ecological terms 'natural areas' (e.g., Wirth, 1945: p. 485). Natural areas were originally thought of as the physical location of plant and animal communities, and this idea was adopted by human ecologists to describe the living environment of human communities. Natural areas are then understood as areas that are naturally grown environments of a community. In the context of human ecology, 'natural' does not have a biologistic meaning, but the natural areas of communities are natural in that sense that they appear to be natural, but are shaped by human interaction. Within these areas, specific norms, values, codes of acting, and institutions are cultivated. Examples for natural areas within a city are segregated areas of specific communities; prominent descriptions of, for example, gangs (Thrasher, 1927), Jewish communities (Wirth, 1928), and Black communities (Frazier, 1932) were done for Chicago by the Chicago School of Sociology.

Competition and Cooperation

Two central ecological concepts, competition and cooperation, were already mentioned in the above description of the structure of communities. Robert E. Park explicitly refers to Charles Darwin to trace the principle of "competitive cooperation" (Park, 1936: p. 3) as a guiding principle of human life – a principle that, according to Park, is per se sociological (Park and Burgess, 1921: p. 194; Park, 1936: p. 2f.) and was used by Darwin (1937: p. 85) to describe the mutual dependency of species in plant and animal communities.

According to human ecologists, competition and cooperation are features of both plant and animal communities and human communities. Competition is understood as a principle that characterizes the simultaneous existence of species. Species compete for the best position in a given environment, both in terms of food and reproduction. Transferred to the analysis of human communities, competition is mainly understood in economic terms: each individual within a community strives for the best possible economic position.

But as plant and animal ecologists observed, it is not only competition that characterizes communities. In order to survive in the best possible way in a given physical environment, species were thought of as cooperating with other species around them. By cooperating, species were able to improve their position within the community. For human communities, cooperation becomes manifest, e.g., in functional differentiation and economic specialization.

Dominance

The relation of the species within a community is additionally characterized by the principle of dominance. Ecologists assumed that in each natural area there exists one species of dominance. This assumption includes the concept of a hierarchy of species in a given environment: one species dominates the others and is thus the head of a specific order, the other species being subordinate to the dominating species in the respective community. Using the principle of dominance, human ecologists describe the social structure of a community. Transferring the main aspects of the principle of dominance to human communities, Roderick McKenzie argues that each community has its own social order and a dominating form of occupation: in communities of hunters and gatherers, communities tend to be small and of temporary character. In agricultural communities, the communities' character is more permanent. In communities with trade and commerce as dominant form of occupation, they are even more permanent

and concentrate at transportation hubs like streams, railroads, etc. (McKenzie, 1968: p. 5).

Succession

Another principle formulated by plant and animal ecologists is that of succession. If the principle of dominance describes the social structure of a community, the principle of succession describes its temporal-spatial structure. The concept of succession is used by ecologists to explain the growth of plant and animal communities or, in other words, the changes a community goes through in relation to time (change of community) and space (community's habitat). Human ecologists applied this model to human societies to explain the growth of industrial cities like Chicago at the beginning of the twentieth century and to the related changes in the social structure of the society.

Based on this ecological concept, models of city growth were formulated. One influential model was designed by Ernest W. Burgess (1925) who conceptualized the city as comprising of concentric zones. Burgess used the model to explain the growth of industrial cities by emphasizing the processual character of a city's development. To Burgess, a city comprises different zones, each zone being the natural area of a specific community and a certain form of land use. The location of a community is a result of the communities' competition for land use and dependent on the value of land in the respective zone. The growth of population, caused by immigration and a positive birth rate, leads to a spatial expansion of the city over time. This processual development was thought of as being regular and occurring 'in cyclic fashion' (McKenzie, 1968: p. 31).

Centralization/Decentralization

The physical form of the locations of human communities and its development imply processes of centralization and decentralization. The tendency to centralize was understood as characteristic of human communities, resulting from "the tendency of human beings to come together at definite locations for the satisfaction of specific common interests" (McKenzie, 1968: p. 26). In societies of the early twentieth century, the central location was a city's downtown area with shopping, entertainment, and business facilities. In the course of the development of cities, different zones loose and gain importance, thus leading to a process of centralization and decentralization of the whole city (Burgess, 1925; McKenzie, 1968).

Reasons for Using Social Ecology in the Social and Behavioral Sciences

At the beginning of the twentieth century, ecology and its concepts were an influential factor for the formation of social and behavioral sciences. Social scientists were confronted with social phenomena so far unknown to them in the late nineteenth and early twentieth centuries. In the course of industrialization, both the relationships between different individuals in a society and between individuals and their physical environment changed. A rapid growth of cities and the transformation of the social structure were observable.

The adaptation of ecological concepts for the analysis of human societies proved appropriate because of two reasons: the ecological theories describing the development of animal and plant communities gave an analytic framework to explain the interrelatedness (1) of individuals and groups within a community and (2) of the community and its environment. By using ecological concepts of how communities develop, different phases of this process could be distinguished and a temporal dimension could be added to the analysis of human communities. Thus, it was possible to describe the development of a society as a process and not as a mere sequence of static stages. Additionally, by analyzing the interrelation of a community and its physical environment, the spatial dimension of the development of human societies were taken into account.

Within the social and behavioral sciences, social ecology was most frequently used in sociology, namely, by the Chicago School of Sociology (Park and Burgess, 1921). But it also altered the methods and research topics in economics, geography, anthropology, or psychology. In general, understanding human communities as interrelated with their environment was the substantial change in regard to contents in these disciplines.

In sociology, ecological concepts and metaphors helped the young discipline to develop coherent theories and models of the development of human societies. Roderick McKenzie (1925) emphasized the difference between ecology and human ecology and formulated distinctive characteristics of an ecological analysis of living species: to him, the distinguishing skills of humans were the ability to be mobile and to adjust the habitat according to the own needs – skills that plants do not and animals hardly possess (McKenzie, 1925: p. 64). This ability enables human individuals to adjust the environment according to their needs; this alters the relationship between humans and their environment and marks a central difference to plant and animal communities' relation to their respective habitat.

The spatial and temporal dimensions of community development were thus the topics of human ecological research as carried out by the Chicago School of Sociology (McKenzie, 1925: p. 64). Phenomena related to urbanization, central for the studies of the Chicago School, were interpreted using ecological concepts. For example, the city's spatial expansion and its social effects were explained with the help of the concepts of succession and centralization/decentralization.

The forms of using ecological concepts differed: on the one hand, the concepts of ecology were applied to the study of human communities with only slight changes: the community was taken as the basic unit of analysis, and the mutual dependency of the community's members was researched in its relation to the spatial environment and its temporality. On the other hand, the terms of ecology were used in a metaphorical way to describe the human environment: Burgess speaks about the 'metabolism of the city' (Burgess, 1925: p. 48) when describing and explaining the processes of a city's expansion and the mobility of its population. The metaphor of a metabolism refers to the intrinsic logics of change of a city's development.

The merit of social ecology as developed by the Chicago School of Sociology was the fact that it provided a terminology and a methodological framework for the analysis of social processes in industrial societies, especially in the context of urbanization. The sociological concept of segregation, until today widely used by social scientists to explain sociospatial phenomena like the spatial distribution of social groups according to economic capital, was developed on the basis of ecological concepts.

In early demography, an important topic of research concerned the distribution of a community's population within a given environment and during the course of the day. Thus, both the spatial and the temporal distributions of the population were in focus. Understanding the human community as a group that follows the principle of succession within a given environment enabled the researchers to explain mobility in a city: in the course of the development of a community, various social groups compete for land in, e.g., a city. Depending on the social order of the community, each social group is assigned a specific natural area. Parallel to the growth of population, the location of the social groups and their specialization extend. Thus, mobility as phenomenon of community development is bound to demographic developments and economic and social differentiation. Empirical studies researching the spatial patterns of mobility of the city's inhabitants were part of demographic research.

In the 1920s, ecology also influenced the research carried out in geography, with Harlan H. Barrows (1923) even understanding geography as synonymous with human ecology. Here, ecological concepts were used to explain the interrelation of human communities and their geographical environment. In contrast to sociological analyses, it is not only the spatial dimension of a community that is integrated in the analysis (Park, 1967: pp. 69–84), but the geographical environment with its decidedly geographical peculiarities.

The idea that competition and cooperation are structuring elements of community development made social ecology also applicable in the field of economics (Boulding, 1970). In psychology (Barker, 1968; Proshansky et al., 1970) and anthropology (Steward, 1955), ecological concepts influenced the analysis of social behavior and the disciplines' methodology. This includes comparative research of communities, in a diachronic as well as in a synchronic perspective, and the identification of stages in the communities' development patterns.

Methods

Besides influencing the theories of the social and behavioral sciences, ecology also altered the methods applied in the respective disciplines. Park describes understanding and comprehending the characteristics of local community culture as the central challenge of community research. Two different approaches to the study of human communities were established with the help of ecological research questions: a quantitative and a qualitative approach.

The quantitative approach comprised methods to analyze spatial patterns of a community's population. A method used frequently was social area analysis. It was a means to understand phenomena like community patterns and segregation on the basis of census data (e.g., McKenzie, 1923; Shevky and Bell, 1955). In order to improve the results of such studies, Roderick McKenzie even suggested to set up an official statistical office to provide data for research (McKenzie, 1968: Chapter 3).

The qualitative approach was influenced by journalistic practices like on-street-interviewing and study trips to the community in focus. Several empirical studies using fieldwork, observation, and interviews were done at the University of Chicago (Frazier, 1932; McKenzie, 1923; Thrasher, 1927; Wirth, 1928), with this beginning to establish the ethnographic fieldwork as method in the social sciences. Robert Park, working as journalist himself, was an influential figure in establishing methods like participant observation and the usage of fieldnotes as data (e.g., Park, 1967: Chapter 3). In anthropology, a similar change in methods took place: instead of using informants to get data on the phenomenon, researchers started to go to the people themselves.

Generally, there was not a divide between the methods used in human ecological research along the lines of a quantitative vs a qualitative approach. Both sides acknowledged the importance of the respective other set of data and methods used, and often a combination of different methods was proposed.

Reasons for the Loss of Influence

In the course of the twentieth century, social ecology lost influence in the social and behavioral sciences. Four reasons might explain this loss of influence: (1) the approach's inability to deal with phenomena of decline, (2) conceptual problems when dealing with exogenous factors of growth and externally employed forces to control development, (3) a too strong focus on economic factors to explain developments, and (4) the inability to explain internal, subversive processes that counteract processual (in the sense of linear) developments.

Phenomena of Decline

The transfer of ecological concepts to the study of social communities took place during a phase of industrialization and urbanization. The phenomena observed and studied were all phenomena of growth. Burgess developed his model of city growth as an idealized model of Chicago that only works under the condition of growth. Succession – spatial expansion and population growth – is one of its main features. A decline of the community in terms of numbers and spatial dimension is understood as a result of the community's cyclical development and causes economic instability and social disorder and unrest. According to social ecology and using the metaphor of an organism's life cycle, this process is comparable to the death of the organism.

In times of economic and demographic decline and shrinking settlements, observable in many societies in the late twentieth and early twenty-first centuries, the basic ecological assumptions can in fact explain phenomena like shrinking cities and the destabilizing effects of deindustrialization and economic decline. But they cannot be used to analyze the

complex processes in which humans interfere with the processes of decline in order to cope with the effects of population decrease and deindustrialization: as soon as externally controlling forces like global financial crises, natural disasters, or the like enter the stage, ecological analysis reaches its limits.

External Factors to Control Development

In ecology, growth as central aspect of the development of communities is understood as endogenous, i.e., as an internal factor influencing the process of development. Again taking Burgess' model as reference, city growth is accompanied by the expansion and segregation of social groups within the physical environment. The tendency to centralize and decentralize is based on economic factors like land value and not on controlling influences by e.g., city planners. In the course of the twentieth century, city planning was an increasingly important task to cope with the effects of urbanization. In order to improve the living conditions in cities, a number of institutions were set up to control and regulate a city's development.

Economic Focus

Ecology used economic arguments to explain the development and the structure of communities: the more economic capital people possess, the farer away from the city's core they live and the richer the communities in the suburban fringes. Human ecology adopted this argumentation to explain the social and spatial structure of human communities. In the course of disciplinary differentiation, economic explanations were said to be not sufficient any more. The development of human communities and their settlements were increasingly understood as a result of a complex set of economic, social, ecological, political, and cultural factors which made new conceptual approaches necessary.

Forces Counteracting Processual Development

Ecological analysis of communities in general and human ecological analysis in particular understood the structure of communities as homogenous, comprising a fixed hierarchy. Not in focus were the continuous internal struggles for dominance, to be observed in the parallel existence of hegemonic and subversive discourses and in the differing human practices within a community. Thus, neither the various forms of power and counterpower nor the peculiarities of an individual's everyday practices can be taken into account in ecological analyses, among other things because the community is the unit of analysis and not the single individual.

Follow-Up in the Late twentieth Century: the Successors of Social Ecology

In the course of the twentieth century, social ecology lost influence in the social and behavioral sciences. Although the general idea of social ecology – the interrelatedness of human communities and their spatial environment – was still used as explanatory model, research with an explicitly ecological approach was generally secondary. But it also had successors. The successors can be differentiated into a direct modification of social ecology, personal successors, and thematic successors, exemplifying different forms of influence of social ecology. A prominent personal successor is Herbert Blumer. Based on the works of George Herbert Mead, he developed further the concept of symbolic interactionism and was highly influenced by the two Chicago Schools, those of Sociology and of Philosophy. Prominent thematic successors are the sustainability studies and the subdiscipline of environmental sociology. Both disciplines emerged in the second half of the twentieth century.

Modification of Social Ecology

Later researchers modified social ecology in the social sciences as used at the beginning of the twentieth century. In these later researches, the original concepts of ecology and their adaptation for the study of human societies were criticized as being too simplistic (Hawley, 1944). Additionally, a more macro-level approach was taken on the analysis of communities within a given environment, emphasizing the collective dimension of communities (Hawley, 1986). Central topics of research were the organization of society, understanding it as a system, and the interrelation of functionally differentiated parts (Duncan et al., 1959).

Symbolic Interactionism

A different form of follow-up can be seen in the case of symbolic interactionism, embodied by George Herbert Mead and Herbert Blumer. Mead and Blumer, both connected to the Chicago Schools of Sociology and Psychology, developed a theory of human interaction that was later called symbolic interactionism (Blumer, 1969). In general, Mead's and Blumer's interest was in the forms of human interaction within a given environment, a topic not far from the research interests of human ecologists. According to symbolic interactionism, an individual's personality is formed within society, i.e., a human community. A central characteristic of human communities is interaction, among other things with the help of symbols. By constantly acting and interacting, social norms and values are created. Mead understands gestures as the initials of acting and is with this argument critically referring to, among others, Charles Darwin. Thus, both human ecology and symbolic interactionism share Darwin as intellectual predecessor and a general interest in the interrelation of human individuals in a community and a given environment.

Sustainability Studies

Since the 1990s, sustainability studies are a new field in which a renaissance of social ecology can be noted. Interestingly, an early article by Radhakamal Mukerjee (1932) already stresses the central aspects of sustainability studies, identifying them as topics of ecological research. By referring to plant and animal ecology, Mukerjee stresses the fact that nature has its own cycle of development. If humans interfere too much with this cycle, they tend to exhaust natural resources, which ultimately destroy the basis of human life (Mukerjee, 1932: p. 353). By demanding a 'bioeconomic cooperation'

(Mukerjee, 1932: p. 353) of humans and nature, he anticipates the sustainability movements of the late twentieth and early twenty-first centuries. By conceptualizing the society as comprising an ecological, an economic, and a social dimension, Park (1936) formulates what will later be the central topic of sustainability studies.

Environmental sociology, thematically related to sustainability studies, is an additional subdiscipline using ecological concepts (Catton and Dunlap, 1978).

Abstract

Critical social enquiry (CSE) connotes research frameworks that originated from the critical social science paradigm and those that have been influenced by feminist, antiracist, anticolonial, poststructural, and postmodern perspectives. This article traces the development of various frameworks of CSE such as action research, participatory action research, and community-based action research associated mainly with critical social science and antioppression research that blends the influences of the critical social science with other theoretical perspectives identified above. These frameworks share a commitment to community participation, social justice, and challenging existing ways of conducting research.

Introduction

The term critical social enquiry (CSE) connotes research frameworks that originated from the critical social science paradigm and those that have been influenced by feminist, antiracist, anticolonial, poststructural, and postmodern perspectives. The initial part of this article presents some of the research frameworks such as action research (AR), participatory action research (PAR), and community-based action research (CBAR) associated mainly with critical social science. The latter part of this article presents the newest form of CSE; anti-oppressive research (AOR) that blends the influences of the critical social science paradigm with the varied theoretical perspectives identified above. All of these frameworks share a commitment to community participation and strive to democratize knowledge, raise awareness of processes of oppression, and engage in social justice (Lavoie et al., 2010). The areas of each approach discussed focus on their basic definitions, roots, methodologies, and limitations.

Critical Social Enquiry

CSE is defined by Cannella and Lincoln (2009) as any research that recognizes the operation of power as reifying unjust and oppressive social conditions as social norms. It is also concerned with issues of identity, which are seen as major shapers of structures of oppression (Cannella and Lincoln, 2009). It is concerned with the emancipation of marginalized people and is firmly political in its intention and process (Alvesson and Sköldberg, 2009; Strega, 2005). Carroll (2004) provides three overlapping images of the critical social inquiry: oppositional, radical, and subversive. He describes the oppositional image of critical inquiry as research, which opposes the status quo through the investigation and critique of social structures and practices of domination. In this image, researchers align themselves politically with the oppressed. The radical image or analysis investigates the challenges researchers faced when exploring the deeper systemic factors influencing oppressions. Thirdly, the subversive image looks for strategies to unsettle the existing arrangements by interrogating 'common sense' binaries that seek to normalize the status quo (Carroll, 2004: p. 3). This process opens doors to an alternative understanding of reality.

Alvesson and Sköldberg (2009) provide an overview of the influence of critical theory in research. They argue that critical theory views people as manipulated, objectified, passive, and conformist in relation to dominant forms of rationality. However, it also views people as having the potential to be autonomous, reflexive, reflective, and critical. Although critical theory is usually thought to be more appropriate for qualitative research, it can also be used in quantitative research.

The history of critical research, which sought to contest entrenched power, can be traced back to the nineteenth century (Carroll, 2004). It originated from sociology, psychoanalysis, philosophy, economics, and aesthetics and was combined into the social science research environment of the Frankfurt school at the end of the 1920s (Alvesson and Sköldberg, 2009). The Frankfurt school critiqued positivism and developed critical theory that was philosophically informed and politically significant (Alvesson and Sköldberg, 2009). Leaders in critical theory included figures such as Marx, Weber, Kant, Hegel, Freud, and Habermas (Alvesson and Sköldberg, 2009). For an example of critical theory written by a social worker refer to Fook (2002).

Since the 1990s, there has been an emerging influence of poststructuralism providing a more practically grounded radicalism to inquiry (Denzin and Giardina, 2009; Ferguson, 2003). Cannella and Lincoln (2009) also note the influence of indigenous and postcolonial perspectives that view the foundations of social enquiry situated in colonial relations of power (refer to Smith, 1999). This new thinking has significantly influenced and transcended the purpose of CSE.

The purpose of CSE has undergone a significant change from its original intent. The purpose has shifted from social justice and empowerment of communities also to include attention on challenging disempowering social relationships that serve to maintain status quo. The purpose of CSE, according to Cannella and Lincoln (2009), is to illuminate the processes of power construction and how these processes disempower groups of people, their knowledges and ways of being. It seeks to uncover myths, reveal hidden truths, and help people change the world for themselves (Strega, 2005). In CSE, knowledge is presumed to be influenced by sociohistorical and political contexts and implicated in and organized around relations of power (Carroll, 2004; Denzin and Giardina, 2009). CSE, therefore, works toward deconstructing discourses, which

maintain these power relations and myths to influence public consciousness and transformation (Cannella and Lincoln, 2009). In this way, CSE opposes not only the traditional notions about the neutral nature of research (Alvesson and Sköldberg, 2009), but it also challenges notions about the neutrality of the researcher (Denzin and Giardina, 2009). Critical social researchers take a stand to change the world, not just interpret it, in ways that resist social injustice and celebrate freedom and democracy (Denzin and Giardina, 2009).

Alvesson and Sköldberg (2009) speak of some of the limitations of CSE. They argue that critical inquiry has the ability to reinforce or question established ideologies without actually adopting a position with either, since it focuses more on preventing research from contributing to dominance rather than on actually overcoming existing dominance.

Another major limitation identified by Ferguson (2003) about CSE and critical theory is its emphasis on negative critique. He argues that the prescribing nature of critical enquiry about what should not be done instead of what can be done and how presents a problem. It may be difficult for change to actually happen in the current sociopolitical climate with the idealized image of practice supported in CSE (Ferguson, 2003).

Action Research

AR is a process that "gives credence to the development of powers of reflective thought, discussion, decision and action by ordinary people participating in collective research on 'private troubles' that they have in common" (Adelman, 1993: p. 8). This definition focuses on developing critical consciousness and developing the capacities of people to take action on problems. It is a collaborative approach that endorses "consensual, democratic, and participatory strategies to encourage people to examine reflectively their problems or particular issues affecting them or their community" (Berg, 2007: p. 224) paying special attention to process. Reason and Bradbury (2008) view AR as less of a methodology, but more of an orientation to inquiry, which seeks to create participative communities focused on action, reflection, and practice in the pursuit of practical solutions to issues of concern. AR is also about creating new forms of understanding for reflection, action, and theory (Reason and Bradbury, 2008).

Adelman (1993) notes, "Kurt Lewin (1890–1947) created the term 'action research' in 1934." It has evolved as a research framework utilizing many different traditions like psychology, anthropology, and sociology (Berg, 2007). Frameworks that use principles of AR include civil rights and feminist movements; liberationist adult and trade union education; postcolonial and critical race theory; and antiwar and ecological protests as well as the student democracy movement (Gayá Wicks et al., 2008).

The purpose of AR is to change or improve what it seeks to study (Berg, 2007: p. 226). In AR, researchers stand with and alongside communities of study (Berg, 2007). Reason and Bradbury (2008: pp. 3–4) discuss critical values that shape AR such as the emphasis on the engagement of people in collaborative and transparent relationships that open up new spaces for dialogue. Two main themes in AR are the importance of practice and life experiences and the web of relationships, events, influences, role models, and experiences in the process of research (Gayá Wicks et al., 2008). Action researchers place life experiences among the primary influences that underpin their research (Gayá Wicks et al., 2008).

Berg (2007) describes three strategies of conducting AR as "technical/scientific/collaborative", "practical/mutual/collaborative/deliberate", and "emancipating/enhancing/critical" (p. 231). In the technical/scientific/collaborative strategy of AR, the researcher identifies a problem using a prespecified theoretical framework and collaborates with a practitioner. The practitioner relays the information of the study to the group. Neither the practitioner nor the community are consulted on the urgency or relevance of the issue, as it solely relies on the expertise of the researcher. In the practical/mutual collaborative/deliberate strategy, the researcher and practitioner define the problem and assess the situation together. The practitioner then informs the community but only in the implementation stage of research. The third strategy, the emancipating/enhancing/critical AR, "embraces a greater concern for empowering and emancipating stakeholders working with the practitioner" (p. 231). As suggested by Berg (2007), this strategy emphasizes involvement of community in identifying and defining issues most critical to their lives as well as working with the community in undertaking research and action on the issue. The emphasis in this strategy is on developing critical consciousness and addressing issues of power between the researcher and the community. While Berg (2007) has described these strategies as theoretically distinct with varying foci, in reality, the research process could look different with researchers using combinations of these strategies. For instance, instead of a researcher being invited to work with a community, a researcher may define the problem with a practitioner and then focus on developing critical consciousness among community members.

Reason and Bradbury (2008) view AR as an emergent process that cannot be predetermined as the methodology of research is developed through the understanding of issues developed by the community and researcher. It uses traditional methods of data collection but have nontraditional orientations and purposes (Berg, 2007).

One of the limitations of AR identified by Reason and Bradbury (2008) is its vulnerability to being co-opted by dominant groups to maintain the status quo. Another limitation of this approach is the existing belief among social scientists that AR is only activism and void of rigorous theories and methods (Levin and Greenwood, 2011). Levin and Greenwood (2011) note that the lack of theoretical and methodological contributions that can be gained through its process can deter researchers from embracing it. Finally, Rutman et al. (2005) critique the approach for its belief that it is possible to achieve a solution that will address the issues experienced by all people involved. This belief fails to consider the operation of power within the community, therefore, potentially affecting engagement of all community members in research and action (Rutman et al., 2005; Tandon, 2008; for an example of AR, see Ku, 2011).

Participatory Action Research

PAR represents a philosophical approach rooted in social justice bringing together inquiry, learning, critical analysis,

community building, and social change (Rutman et al., 2005). It is a critical strategy deeply rooted in the experiences of the colonized 'other' (Carroll, 2004) providing a framework for people who seek to overcome oppressive situations and understand how social forces operate (Tandon, 2008). Terms used by theorists of PAR include empowerment, critical consciousness, transformation, conscientization, dialogue, social action, and participation to characterize different aspects of the research (Tandon, 2008).

PAR is informed by many social struggles and movements (Brydon-Miller et al., 2011). PAR was formed through the efforts of mass social struggles over the independence of colonies in Asia, Africa, and Latin America at the end of World War II (Tandon, 2008). According to Tandon (2008), it was not until the 1970s that PAR became popular as a result of the influence of Paulo Freire (1970) who developed it as a tool for fighting oppression through the practice of adult education and community organizing in Latin America. PAR has also been shaped by the social struggles of feminist, labor activist, civil rights workers, and other activists (Brydon-Miller et al., 2011).

The explicit aim of PAR is to bring about a more just society in which no group or class of people suffer from the deprivation of life's essentials, such as food, clothing, shelter, and where all enjoy basic human freedom and dignity (Alvarez and Gutierrez, 2001). PAR also recognizes the necessity of marginalized people be involved in the process of change (Brydon-Miller et al., 2011). Therefore, PAR's methodology focuses on collaboration, political engagement, and an unfailing commitment to social justice and values the collaboration and knowledge of marginalized people affected by an issue (Brydon-Miller et al., 2011).

According to Gutierrez (2003), PAR projects differ from other types of research in the significance given to process. There are many different ways a researcher can begin a PAR (Gutierrez, 2003). Researchers could either be invited into the community as an outside consultant, be a well-informed member of an organization on the issue, or be invited to work with community members (Gutierrez, 2003). However, Gutierrez (2003) notes that it is not how one begins a research project that is of importance but how the process develops democratically over time.

During the initial part of the project, the researcher engages and organizes the community's attention on an issue similar to a community organizer (Gutierrez, 2003). The researcher then meets with community members to discuss the issue and engage them in deciding a course of action most relevant to them. Researchers and community members then discuss and plan their nature of inquiry, methods of data collection and analysis, and how they will use the findings of their inquiry. Although there has been little written about approaches and methods used by researchers, Photovoice has been a popular method used by many researchers. Photovoice is a method whereby people photograph their own realities and use those photographs to engage in dialogue and explore ways of taking action (Alvarez and Gutierrez, 2001; for information on photovoice, see Wang, 2006).

PAR shares with AOR an understanding that researchers are knowledge producers and are positioned in a power relation for change (Rutman et al., 2005). In PAR, there is less emphasis on locating the researcher than there is in AOR. However, PAR holds the assumption that the researcher and the researched have already developed a critical consciousness of power and that they would not be working together if they were not closely allied (Rutman et al., 2005). This implies that the exercise of locating oneself as a researcher is unneeded during the process (Rutman et al., 2005).

Researchers who believe in PAR have responded to the critique on lack of methodological rigor in the enquiry. Gutierrez (2003) provides insight into how methodological rigor is evaluated for this form of enquiry. She states that validity of data in this approach can be measured by participants' empathy levels, understanding of the intent of a question (face validity), willingness to give needed information (construct validity), triangulation of different methods, and interactive knowledge. It also depends on whether the knowledge shared can act as a catalyst for empowering participants to overcome obstacles to oppression.

Alvarez and Gutierrez (2001) note that many researchers, drawn by the goals and potential of PAR may engage in this sort of research without fully understanding it and subsequently risk reproducing dominance. Alvarez and Gutierrez (2001), Park (1993) and Rutman et al. (2005) argue that without a strong understanding of PAR, researchers risk tokenizing community members. Therefore, it is imperative for researchers and the researched to spend time working through and agreeing on how to conduct research.

Rutman et al. (2005) critique PAR's attempts to create a democratic work environment may not negate power differentials in responsibility, authority, and inability to contribute equally toward research due to life circumstances. Recognizing that there are power differentials in the relationship among the community and between researchers allows for more honest discussions in clarity about roles within a research team. For an example of PAR refer to Gellis (2001).

Community-Based Action Research

The literature on this approach uses different terms such as CBAR, community-based participatory research, and community action research to denote research done with communities. CBAR is an approach to research that focuses on local action and strategies to address specific problems in specific situations (Stringer, 2007). Stringer (2007) notes that cooperation and consensus are the primary orientation of this research and that it provides a climate suitable for groups to work together to achieve a set of goals. Through CBAR, participants learn the skills to engage in research that they can later apply to other issues. CBAR recognizes the importance of this and therefore the importance of members acting as key partners in research (Briar-Lawson et al., 2010).

CBAR evolved out of similar traditions mentioned in the PAR (Reitsma-Street and Brown, 2004). However, CBAR seems to have tailored its focus more on local and community action approaches to enquiry and also emphasizes cooperation and consensus instead of more structural change as is more the goal of PAR (Reitsma-Street and Brown, 2004; Stringer, 2007).

Reitsma-Street and Brown (2004) argue that the purpose of CBAR is community well-being and for Briar-Lawson et al. (2010)

and Stringer (2007), it also means emancipation and community building, such as capacity building, asset enhancing, and social capital development. Its four values are social justice, agency, community connectedness, and critical curiosity for change (Reitsma-Street and Brown, 2004). Through group dialogue people learn about oppression, identify common connections to their own lives, and envisage a social world that accounts for those connections.

Reitsma-Street and Brown (2004) state that fundamental to this research is the careful and continuous negotiation between whose voice is emphasized, what strategies are utilized, and on whose behalf research is conducted. Unique to CBAR, and different from PAR is its intentional effort to include many participants and capture the reactions of multiple audiences in the recognition that among community members, there are "sharp differences in the lifeworlds and futures of its members" (p. 304).

Reitsma-Street and Brown (2004) also describe three approaches to inquiry used in CBAR; the first set uses commonplace qualitative and quantitative methods such as life-history narratives or statistical analysis of communities. The second set uses sustained, democratic dialogue, and other shorter research activities. The third deals with theorizing work in research. Through democratic dialogue on a local level, data is interpreted in a way relevant to different audiences.

Like any other research all of the approaches of CSE whenever undertaken with academic or institutional partner require ethics approval, which may change the way CSE is conducted (Flicker et al., 2007). Minkler (2004) and Flicker et al. (2007) have discussed the limitations of using ethics protocols used for conventional research for community-based research such as CSE. According to them, issues ignored by the current protocols include questions such as who is initiating the research, whether the issue selection is driven by the community, who benefits the most from the research, whose voice is being heard and represented, and what constraints do community members experience regarding involvement. Other ethical issues relate to the sharing and release of findings, use of data and representation of the community through the data, challenges in the action dimensions of research, and insider–outsider tensions (Minkler, 2004; Flicker et al., 2007). However, indigenous researchers have addressed these ethical dilemmas and have created guidelines in response to these issues, for instance in the Canadian Institutes of Health Research guidelines which promote accountability, transparency, and partnership in research (Canadian Institutes of Health Research, Natural Sciences and Engineering Research Council of Canada, and Social Sciences and Humanities Research Council of Canada, accessed December 2010, http://www.pre.ethics.gc.ca/pdf/eng/tcps2/TCPS_2_FINAL_Web.pdf).

CBAR values subjective interpretations of relevance and authenticity by the community, qualitative research standards of trustworthiness and congruence, and quantitative statistical standards of reliability, validity, and generalizability as its standard practice (Reitsma-Street and Brown, 2004).

Reitsma-Street and Brown (2004) critique CBAR for its almost exclusive focus on local change efforts and its failure to discuss how one arrives at an understanding of injustice for a certain situation and strategies to change them. CBAR is then at risk of being "co-opted for the benefit of those already holding privilege and power" (p. 316).

A challenge identified by Briar-Lawson et al. (2010) is attaining and maintaining community-based processes. The time commitment required of participants can be a major deterrent to participating, as participants are required to balance many practice and research demands. Stringer (2007) points out the "pressures of bureaucratic life, the limitations of resources, and the competitive push for career advancement" are constantly working against "attempts to humanize and democratize research processes" (p. 190). For an example of CBAR refer to Reitsma-Street and Neysmith (2000).

Antioppressive Research

AOR has emerged as the latest form of CSE. It draws on a number of theoretical frameworks in the pursuit of research and recognizes a relationship between producing knowledge about the world and the actual practice of doing research exists (Potts and Brown, 2005). It also recognizes that knowledge is socially constructed and located within power relations (Potts and Brown, 2005; Strega, 2005). Knowledge is also considered to be situated and subjugated by social location as a result of experiences of privilege and oppression (Moosa-Mitha, 2005).

AOR is as much concerned about the process as it is the outcome. The process itself is viewed as an outcome with the understanding that social justice cannot be achieved without the research process being purposeful and intentional as the focus of the study could potentially objectify 'the oppressed' otherwise (Potts and Brown, 2005: p. 267). Potts and Brown (2005) present three main tenets of AOR. First, AOR is social justice and resistance in the process and outcome. Second, it recognizes that all knowledge is socially constructed and political. Third, the process in AOR is all about challenging oppressive power relationships.

AOR is influenced by critical theories as it makes the connection between knowing and doing (Moosa-Mitha, 2005). However, AOR goes beyond critical theory in recognizing the importance of the subjective and specific including sociohistorical experiences, in emphasizing fluidity and contesting binary constructions of reality (Moosa-Mitha, 2005). AOR has also been influenced by emancipatory approaches to research as it promotes the production of knowledge that supports freedom from oppression and is transformative in the material and social relations of research production (Strier, 2007: p. 860).

The goal in AOR is not to find 'truth' but to find meaning and an understanding of power in order to change situations (Potts and Brown, 2005). AOR acknowledges its value position by taking a stance committed to social justice (Potts and Brown, 2005; Strega, 2005). It views knowledge as power, and since there is a relationship between research and knowledge creation, researchers are cautioned about whether they are supporting or challenging existing power structures (Strega, 2005).

AOR, therefore, aims to redistribute power and ownership over the production of knowledge (Strier, 2007). It transforms the way social researchers frame the focus, scope and, outcome

of their work (Strier, 2007). Research conducted from a neutral or objective location is considered unethical (Herising, 2005) as AOR acknowledges that the worldview of the researcher will shape the researcher's epistemological foundation affecting every step of the research project (Strega, 2005). However, this approach believes this can be avoided if the researchers locate themselves (Herising, 2005).

AOR is 'not methodologically distinctive, but epistemologically distinctive' since it questions the relationships of the knower, the known, and those who want to know (Potts and Brown, 2005: p. 283). Since antioppressive researchers are aware of the dynamics involved in the social construction of knowledge, AOR is not a process to discover knowledge, but a political process to 'cocreate and rediscover knowledge' (Potts and Brown, 2005: pp. 261–262). The question of whose voice is being represented in the research becomes a main focus in critical research (Potts and Brown, 2005; Strega, 2005). These researchers consent with the perspectives of indigenous scholars, critical race theorists, and feminists who have raised important epistemological questions about who is allowed to create meanings about the world, whose voice is validated, and how social identities factor into the decision (Strega, 2005). Strega (2005) argues that social justice researchers consider the answers to the questions: "How can I best capture the complexities and contradictions of the worlds, experiences, or texts I am studying? Whose voice will/does my research represent? Whose interests will it serve? How can I tell if my research is good research? Are choices about resistance and allegiance to the hegemony of Eurocentric thought and research traditions?" (p. 199).

In AOR there is 'no research without relationships', meaning that researchers cannot approach a community with the intention of collecting data and leaving (Potts and Brown, 2005: p. 263). The relationship between researchers and the community is one that could possibly be for life as there is no neat and tidy beginning and end (Potts and Brown, 2005). Through strong relationships, the researcher engages people in all stages of research who then formulate research questions and design the study. The ongoing construction of a study design is done from an epistemological understanding of values and recognizes the importance of subjugated knowledges (Potts and Brown, 2005). Viewed from this perspective, research processes become acts of resistance (Potts and Brown, 2005).

The first site of change usually in AOR is the researchers themselves (Potts and Brown, 2005). Becoming an anti-oppressive researcher means challenging one's own perception of self, history, contexts, and actions (Potts and Brown, 2005). Scholars have written about the importance of transparency and accountability of the researcher to the community (Herising, 2005; Potts and Brown, 2005). It is important that ideological and political biases are made visible and that the researcher continually reflects on when and how their beliefs, values, identities, and knowledges impact the work with various communities (Herising, 2005). This would give indication when those beliefs, values, identities, and knowledges need to be disinherited, disavowed, decentered, disrupted, claimed, reinserted, or centered in the work (Herising, 2005: p. 131). However, such quests for transparency may excuse researchers from attending to the complex interrelationships and colonial context of research (Herising, 2005). Therefore, Herising (2005) argues it is important for researchers to move beyond individualized reflection and reflexivity and take a critical stance by considering the multiple histories that shape dynamics of power.

Strega (2005) provides criteria for assessing AOR. Instead of assessing research from positivist standards of validity and reliability, Streg suggests that criteria such as social justice validity, disseminating back the findings in a manner accessible in format and language to the community, and reflexivity in assessing the researcher's own complicity in systems of domination and subordination should be used for assessing AOR. These ways of evaluating research have been criticized by both positivist and postpositivist researchers. Positivist and post-positivist researchers perceive such criteria for evaluating research as 'attacks on reason and truth' (Seale et al., 2004; Denzin and Lincoln, 2012: pp. 8–9) and hold the opinion that their work is free of bias and subjectivity and hence more scientific. See Potts and Brown (2005) for an example of AOR social work studies.

CSE, AR, and Social Work

The purpose of CSE including AR is congruent with the mission of social work practice in that they both are concerned with the emancipation of marginalized people and creating transformative change (Alvesson and Sköldberg, 2009; Carroll, 2004; Strega, 2005). These are not unlike the concerns of critical social work, which include the emancipation of marginalized people, the elimination of structures of oppression, social justice, and transformative change (refer to Fook, 2002; Potts and Brown, 2005). As such, social work practitioners have been encouraged to embrace research as a core aspect of their practice (Brown and Strega, 2005). Social workers can utilize these forms of enquiry as useful tools for practice by for engaging with communities in understanding and exploring issues of relevance to them, building capacities of communities, and galvanizing communities to take action on issues of oppression and injustice experienced by them. Using CSE social workers can bring forward the subjugated knowledges and otherwise silenced voices of marginalized groups on issues that impact their lives. Participatory, empowerment, and transformative components of CSE can also be effectively used to conduct community appraisals, impact assessments of policies, and program evaluations (for more information on transformative evaluation refer to Fetterman, 2002). Overall, CSE provides opportunities for social workers to participate in transformative change; impacting the lives of community members individually and collectively and ultimately transforming society (see Brown and Strega, 2005: p. 10).

Conclusion

The foregoing discussion traces the evolution of CSE from AR, PAR, and CBAR to AOR. While the philosophical foundation of these frameworks originated from critical social science during the course of their development they have been also influenced by feminist, antiracist, anticolonial, poststructural, and

postmodern perspectives. The common thread that binds these frameworks is the commitment to issues of participation, social justice, antioppression, and transformative change. This commitment of CSE is congruent with the progressive mission of social work and could be effectively used by social workers engaged in effecting change.

Abstract

The search of social determinants of health and disease has advanced substantially over the last decade. We present recent theoretical advancements, methodological approaches, and a selection of empirical evidence for the three main research strands: first, social inequalities can explain health differences. Here, we first focus on hierarchical social stratification with regard to socioeconomic and social class differences influencing health, then we extend the view toward nonhierarchical social stratification with regard to ethnocultural differences, lifestyle, and cognitive and noncognitive abilities. We shortly mention social relations and social network as determinants of health. Last, we use the concept of social times to distinguish age, period, and cohort effects in population health. After presenting evidence on contextual social determinants of health, we close with methodological challenges, social policy implications, and translation to practice.

The Field of Social Epidemiology

Health and disease are not only influenced by biological, genetic factors, and health behaviors, but also to an important extent by social and societal characteristics (Amick, 1995). The discipline systematically investigating the social determinants of health and disease is called social epidemiology. The three main fields assigned to social epidemiology are related to social inequalities, social relations, and social time. In this article, the focus regarding the study of *social inequalities* will be to include both the role of hierarchy in health ('vertical inequality,' Section Social Inequalities in Health and Disease), and to extend beyond the traditional concepts of socioeconomic position and social class and include nonhierarchical differentiations such as ethnocultural differences or lifestyle ('horizontal inequality,' Section Nonhierarchic Social Determinants of Health). After that, *social relations* determining health are presented, which can be related to the French school of social sciences developed by Emile Durkheim (1897), where the study of 'social facts' is rooted in a social theory of integration and of regulation (Berkman et al., 2000; Section Social Relations Pertaining to Health Differences). The study of social inequalities determined by age, another nonhierarchical attribute leading to important social inequalities across cohorts and historical periods and particularly visible in age-period-cohort (APC) analyses, will be expanded in a separate section on the role of *social times* in determining health and disease (Ryder, 1965; Section Social Times in Explaining Health Differences). After reviewing a selection of evidence on contextual social determinants of health (Section Micro- and Macrocontextual Views), we close with perspectives on methodology, social policy implications, and translation to practice (Section Perspectives on Methodology, Social Policy, and Translation to Practice).

A core hypothesis based on extensive sets of observations is that, in virtually all noncommunicable diseases, a socioeconomic gradient can be observed in that lower socioeconomic groups have higher incidence or prevalence rates of disease, develop disability with a greater chance, and die at younger ages than higher socioeconomic groups. As people are born into a certain socioeconomic status or are in lower socioeconomic groups for reasons they cannot (entirely) control, these socioeconomic gradients of health and disease are often referred to as *social* or *socioeconomic inequalities*. In a time of increasing inequalities in many countries (Piketty, 2014), these issues are vital for the future of human health. Today it is almost common knowledge and a central result of this discipline that social inequality leads to bad health (Wilkinson and Pickett, 2010), although it can be argued about the appropriateness of the underlying social interpretations (Goldthorpe, 2010) in both academic and para-academic circles.

Considering the wealth of research in social epidemiology over the last decades, this article can only give a broad overview of some of the main lines of research. In the following, concepts and research on how health is influenced by social inequalities will be presented.

Social Inequalities in Health and Disease

When referring to social inequality and impact on health, two main conceptualizations might be mentioned. The first one pertains to a neutral (smooth) vision of inequality where a *vertical* scale of resources (ultimately: income) generates different health outcomes, conceptualized as *socioeconomic position* (Section Socioeconomic Position). The second one, *social class*, relates to more radical class divides (Section Social Class). In this section, we focus on research on social inequalities as hierarchical differentiation, and particularly consider recent theoretical and methodological advancements. Whereas this 'vertical,' hierarchical aspect of social inequality is the most visible result of social epidemiology, the 'horizontal' or nonhierarchical differentiation must be underlined as a source of investigation, and will be discussed in Section Nonhierarchic Social Determinants of Health.

Socioeconomic Position

For Krieger et al. (1997), *socioeconomic position* is defined as an "aggregate concept that includes both resource-based and prestige-based measures, as linked to both childhood and adult social class position" (p. 345). In this tradition, inequality is mainly a hierarchical series of layers pertaining to unequal size of resources able to affect health. Typical measures of socioeconomic position, based on different degrees of resource and prestige, respectively, are education, income, and occupation. The interchangeable use of these indicators in social inequalities research has often been cautioned, as Krieger (2001a) notes that "(g)iven distinctions between resource-based and prestige-based aspects of socioeconomic position and the diverse pathways by which they affect health, epidemiological studies should state clearly how measures of socioeconomic position are conceptualized" (p. 697). Geyer et al. (2006) show in mortality data of Sweden and Germany that income, occupation, and education reflect different social phenomena and their associations with health outcomes relate to different underlying causal mechanisms.

Social Class

The often acclaimed book of Wilkinson and Pickett (2010) is another typical example of a hierarchical conception of social stratification that had been criticized by Goldthorpe (2010) as a stronger definition of social inequality in terms of structured social classes is needed. This tradition develops a social theory of not only based on individual access to resources in a continuous social scale but to a more holistic (if not Marxist) structuration of this access by a number of classes discontinuously positioned in society, having specific borders and closures able to explain the durability of inequality. In this sense, the term *social class* is defined by Krieger et al. (1997) as a "social category referring to social groups forged by interdependent economic and legal relationships, premised upon people's structural location within the economy" (p. 345). This definition implies that, in fact, social classes extend the view of a health 'gradient' and are (with or without Marxist connotations) not only socioeconomic layers but unequal and mutually hostile status groups of individuals organized on the base of groups sharing social identity (language, lifestyle, elements of recognition), temporal identity (durability of the system of positions, homogamy, social immobility), and even political identity (values and political preferences, unions membership, and political action). In this sense, whereas socioeconomic position is often referred to as social 'ladder' that one can climb up (or down), social class reflects both a hierarchical concept and the creation of 'identity divides' with categorically unequal groups of people. This tradition shows larger explanatory ambitions in terms of system of inequalities of resources and of statuses, resilient to equalizing public policies (Goldthorpe, 2010), but may be more effective when its aims are more modest, as shown by Elo (2009) in her survey of class health inequalities, where the advantage of the second tradition is to better underline the effects of convergence and divergence of economic, educational, cultural, and social resources. Before we continue to the nonhierarchical conceptualization of social stratification, let us first review evidence on (hierarchical) socioeconomic differences in health.

Empirical Evidence

The field of social epidemiology has drastically evolved after several hallmark publications documenting the existence of vast health inequalities, perhaps most prominently presented with data of the Whitehall II study of British civil servants (Marmot et al., 1991). Furthermore, early methodological advances came with different indices of socioeconomic inequality (see Section Perspectives on Methodology, Social Policy, and Translation to Practice for recent methodological advancements). The interested reader is referred to two recent reviews documenting social determinants of health and health inequalities in Europe: Mackenbach et al. (2008) and Marmot et al. (2012). In the beginnings of comparative social epidemiological research, often (general) mortality was used as a health outcome. Among the prominent publications in this field is, for instance, a review by, Subramanian and Kawachi (2004). More recent approaches have benefitted from the availability of national registries on cause-specific mortality, but also on large comparative surveys on self-rated health and medical conditions.

In the last decade, the focus of social inequalities research has shifted to nonmortality health and disease outcomes. Concerning the countless studies applying outcomes such as cardiovascular disease or stroke, we have aimed at providing the most relevant studies and further readings in the respective sections. Large population-representative surveys make it possible to use the indicator of self-rated health, e.g., in research on state-level influences on health (Subramanian et al., 2001) or use self-reports to determine socioeconomic differences in the complex old-age syndrome of frailty.

Some recent research has used biomarkers in order to determine to which extent socioeconomic differences translate into bodily changes (see the concept of embodiment; Krieger, 2001b). A few (very selective) examples of outcomes in this field are socioeconomic differences in obesity, hypertension, or grip strength.

Last, one distinct line of research also makes use of psychosocial outcomes of health, such as life satisfaction or well-being, thereby identifying a socioeconomic gradient in, for instance, depression (Lorant et al., 2003).

Nonhierarchical Social Determinants of Health

Extending the view on social inequalities from a hierarchical perspective, population health is not just about income inequalities and social class divides, but also influenced by individual attributes, both within and across social layers. Thus, a more 'horizontal differentiation' relating to nonhierarchical attributes of the members of a society shows that other factors such as ethnicity, lifestyle, and cognitive and noncognitive abilities produce status and health differences.

Research on nonhierarchical dimensions of social stratification and its capacity in explaining health differences has gained importance during the last decade, and nonhierarchical individual factors contributing to social inequalities have been

ascribed more and more importance. In line with the notion to distinguish between proximal and distal causes for health inequalities, one can differentiate nonhierarchical individual attributes that contribute to inequalities in status and health. One line of argumentation relates to the translation of hierarchical stratification to changes in individual attributes, e.g., the level of *stress* which in turn acts as a cause for health inequalities. A prominent advocate of this line of reasoning is Nancy Krieger (2001a). To illustrate this notion, she has coined the concept of *embodiment*, "a concept referring to how we literally incorporate, biologically, the material and social world in which we live, from conception to death" (Krieger, 2001b: p. 672). Another pathway how socioeconomic status translates to individual attributes is related to the notion of control and related concepts (self-efficacy, helplessness, hardiness), and it can be postulated that feeling in control is related to less stress in the sense of Krieger or that control involves material and immaterial resources such as economic power, information, or prestige. A very recent field delving even deeper into nonhierarchical dimensions of social stratification targets possible interactions of genetic and social factors and is under increasing scrutiny in the field of fertility and reproductive health (Balbo et al., 2013), a cross-borders domain where new perspectives for social epidemiology can be found.

Another line of argumentation is evolving from the search of mediators in the socioeconomic position–health relationship. Past research has shown that socioeconomic position is not able to fully explain the health gradient: It is easy to imagine why those at the bottom of the socioeconomic ladder may fare the worst (the classic line of argumentation being that they may have limited access to health care, not enough resources to afford a healthy diet, or face occupational hazards). Yet health truly follows a gradient in that, compared to those at the top of the socioeconomic ladder, being just beneath the top is in many cases already associated with worse health (Marmot et al., 1991). However, the picture gets more complicated if we extend our view beyond restricted work environments (e.g., the London civil servants' population) and compare hierarchies of members of different cultural contexts (e.g., teachers in schools vs company employees). These complexities aside, the health gradient even within a work environment cannot be fully explained by the mere differential availability of socioeconomic resources. Acknowledging this fact, incorporating nonhierarchical individual attributes into frameworks and studies of social determinants of health has been shown to explain larger parts of the socioeconomic health gradient. While individual nonhierarchical attributes are in many cases related to health outcomes regardless of indicators of social class, it is important to bear in mind that many of these attributes are closely associated, and in many cases interact with indicators of social class. In the following, a selection of relevant research on nonhierarchical social determinants of health is depicted.

Ethnocultural Differences

The most prominent differentiations among nonhierarchical concepts of social stratification are certainly ethnicity and race. These factors may on first glance be individual-level factors, however, an overwhelming body of research concludes that it is often the sociocultural context which defines health advantages and disadvantages of native- and foreign-born people. Native- or foreign-born status has multifaceted health implications such as differential access to health care, differences in common health behaviors of the country of residence, and most prominently strong associations with different socioeconomic position. Ethnic and racial differences in health, thus, cannot be investigated without considering sociocultural context factors contributing to these health differences. As an exhaustive presentation of relevant research is beyond the scope of this article, the interested reader is referred to a comprehensive review on the topic in Anderson et al. (2004). Whereas the main strand of research was driven by the ethnically diverse population of the U.S., recent research also considers ethnic differences in health in European countries with a large migrant population. Applying the life course framework to explain ethnic differences in older-age outcomes, important theoretical and empirical contributions have been made investigating outcomes such as stroke (Glymour et al., 2008).

Lifestyle

These individual attributes relate to (un)healthy *lifestyle*, as important health behaviors (e.g., smoking, physical activity, fruit, and vegetable consumption) in many cases follow a socioeconomic gradient as well (Lantz et al., 2001). As one prominent example for the influence of lifestyle in interaction with socioeconomic position, Krueger and Chang (2008) show that high stress levels and unhealthy behaviors (former smoking, physical inactivity) can independently explain mortality. Further, the combination of these risk factors creates a group of individuals at high risk for premature death, thereby acting as a powerful 'toxin' that can only be identified – and targeted – by including both hierarchical and nonhierarchical dimensions of social stratification in explaining health.

Cognitive and Noncognitive Abilities

The rise of searching for individual-level factors contributing to social inequalities in health has certainly been expedited by theoretical advancements in *life course epidemiology*, tracing back adult health to childhood and even pre- and perinatal influences (Ben-Shlomo and Kuh, 2002). In line with this framework, empirical evidence has been gathered that socioeconomic position may vary across the life course and may have different implications for later health outcomes. In this tradition and with the availability of large data sets spanning large parts or even the whole lifespan of respondents, compelling evidence has been gathered that *intelligence*, assessed in early childhood, contributes to a large extent to adult and old-age health. This led to the debate if intelligence is even the 'fundamental cause' of health inequalities (Gottfredson and Deary, 2004) and to defining the emerging subdiscipline of *cognitive epidemiology* (Deary and Batty, 2007). In this tradition, economists are also increasingly applying the social epidemiological perspective in explaining adult socioeconomic differences and health inequalities with the impact of childhood cognitive and noncognitive endowments (Conti et al., 2010).

Social Relations Pertaining to Health Differences

Considering the wealth of research on the associations between social network and health, we will only give a short overview of the roots of this research and its adoption in social epidemiological research.

A framework on how contextual factors shape health has been developed by Krieger (2001b), the so-called ecosocial theory. Today it is widely recognized that social networks shape health and well-being of their members. In fact, this line of reasoning goes back to Emile Durkheim. In his seminal research on suicidal behavior, Durkheim proposed a double-traits explanation based on regulation (capacity to assign oneself attainable goals) and integration (strength of social ties). Socialist but anti-Marxist, the founding father of the French school of social sciences introduced important explanatory factors. At his time, *economic crisis* – because of its effects of reducing the capacity to achieve goals and of generating frustrations and thus anomic behavior, including suicide – and the emergence of a modern society of isolated individuals lacking social commitments and integrative networks have been detected as important explanations of the expansion of suicide in the late nineteenth-century France.

Indeed, social networks cannot be reduced to the functions they provide, e.g., social support, but they have to be viewed in the larger social and cultural context: Berkman et al. (2000) make a plea for a more Durkheimian view on social networks and health, as "it is critical to maintain a view of social networks as lodged within those larger social and cultural contexts which shape the structure of networks. (…) Only then can we fully consider the multiple pathways by which social networks might so profoundly influence health outcomes" (p. 846).

Social Times in Explaining Health Differences

An important methodological challenge from today's point of view is the integration of *time* in general. The discipline faces complex systems of social causality: Social determinants of health evolve over long time lags that are sometimes spanning several decades between the initial causes, often situated in childhood, and their ultimate consequences in late adulthood. Furthermore, social determinants of health follow complex personal trajectories that are influenced by multidimensional social and other risk factors, possible nonlinearities, and reversibilities. On top of these sources of complexity, 'time' is plural: the concept of 'age' transports information about individual 'somatic' *age* that shapes health outcomes, but is also the reflection of being a member of a *birth cohort*, with all life course experiences from prenatal to childhood throughout adulthood (Ben-Shlomo and Kuh, 2002). In addition, it contains information on *historical period*, thus highly diversifying the definitions of time. Moreover, 'age' and 'period' can compete with regard to the stage of country development. It is therefore desirable – yet difficult – to disentangle the effects of age, period, and cohort on health and disease. As a result, an increasing demand for longitudinal data sets, panel studies, life-event analysis methodology, and sophisticated structural models generates large avenues for methodological developments (Oakes and Kaufman, 2006).

One of the important fields in this domain is the renewal of APC models that intend to ways that disentangle effects related to somatic age, historical period, and birth cohort. From the first 1930s discoveries to Ryder's (1965) conceptualization, and traditional modeling proposals, the field of APC has drastically evolved. After 2005, a large renewal in the domain has been allowed by new available multilevel and general linear models (Yang and Land, 2013).

Researchers supporting this trend recently proposed new investigations of health outcomes such as happiness, obesity, smoking habits, cognitive decay, general as well as cause-specific mortality, to name just a few. APC research aims for instance at detecting birth cohorts at risk that entered adulthood in a period of unsafe health environment, for instance an epidemic outbreak, facing stronger exposure to potentially lethal infections, whereas earlier and later (luckier) cohorts faced a better context of health socialization. This kind of research allows both assessments of public health policies and forecasting on health conditions of aging populations. Extending the view of social inequalities to a comparative perspective across historical time, it is of great interest to know if birth cohorts differ in given advantage or disadvantage compared to earlier or later birth cohorts, that is, if there are social inequalities between generations (Chauvel and Schröder, 2014). The resulting question is the extent to which these inequalities are due to individual-level factors such as educational attainment or, conversely, contextual-level factors such as historical economic situation or welfare regime, and to determine if these disadvantages are, over the life course, permanent or transitory (Chauvel et al., in preparation).

Micro- and Macrocontextual Views

The field of social epidemiology has benefitted from a long tradition of studies investigating contextual influences on health and disease. In the following, a selection of recent evidence on the association of neighborhood factors and health will be presented. After that, comparative evidence on the influence of country, i.e., population-level influences such as types of welfare regimes, will be outlined.

Neighborhood and Area

Extending the social network view on individual health differences briefly outlined before (Section Social Relations Pertaining to Health Differences), a growing body of research investigates health effects of environmental surroundings, area, and neighborhood, applying usually multilevel modeling. Diez Roux and Mair (2010) offer a comprehensive review on how neighborhood can contribute to social and ethnic inequalities in health. They provide a framework that explains how residential segregation by race/ethnicity or socioeconomic position is linked to neighborhood physical environment (e.g., quality of housing) as well as social environment (e.g., safety/violence). This in turn, in interaction with individual behavioral mediators and stress, influences health outcomes (Diez Roux and Mair, 2010). With regard to other health outcomes,

it may be worth to mention a recent study investigating causes for neighborhood inequalities in later-life cognitive function by applying a well-designed multilevel mediation analysis (Clarke et al., 2012).

Neighborhood studies face structural and methodological challenges in the search for true *causes* of health differences related to neighborhood. Oakes (2004) cautiously notes pitfalls of common multilevel models in estimating neighborhood effects and suggests both a counterfactual causal framework and a series of advances to overcome these pitfalls, proposing randomized community trials as gold standard.

Country, Nations, Institutions, and Welfare Regimes

Comparative analyses of socioeconomic gradients in mortality rates show the influence of the welfare regime on the health and health inequalities of its inhabitants (Eikemo et al., 2008). Country of residence does not only reflect different historical steps of socioeconomic development that still influence the present situation (*path dependency*, Pierson, 2000), diverging cultural lifestyles and food habits, but indeed countries are shaped by categorically different ways of organization of institutionalized solidarity and welfare regimes (Esping-Andersen, 1999). Much evidence points to the fact that institutions matter for health and successful societies (Hall and Lamont, 2009). Indeed, the study of comparative decommodification of health systems, insurances, pensions, education, etc. had been able to explain how similar countries in terms of economic development have had divergent outcomes in terms of quality of life and of health performances. Health and life expectancy depend to an important extent on national social policies, such as access to and quality of health care or tobacco control, or simply the level of living standards of older people via public and private pensions systems.

Two recent developments target, first, the use of comparative approaches to directly estimate the differential impact of country and national indicators on health outcomes, and, second, the use of the life course framework to investigate life course influences on later health outcomes.

With regard to the first line of research, the use of large national registries makes it possible to not only consider country of current residence, but also country of origin. Extending research on the so-called U.S. Stroke Belt (a number of U.S. states with high stroke rates), Glymour et al. (2007) show that residence in one of these states in childhood predicts stroke even after moving to a 'healthier' state later in life. The importance of these life course effects matters especially for stroke and other education-dependent outcomes, such as old-age cognitive function or dementia mortality, such as state-level quantity and quality of education.

Another recent comparative study used a summary health policy performance indicator for 43 countries that geographically belong to Europe to determine the extent to which survival is dependent upon national health policies. The authors conclude that health policies importantly contribute to survival by showing that, overall, Sweden, Norway, and Iceland perform best, whereas Ukraine, Russian Federation, and Armenia perform worst (Mackenbach and McKee, 2013).

With regard to the second line of research, life course theory offers plenty of possible hypotheses to test the influence of state-level life course factors on later health outcomes. It is for instance possible that transitory economic conditions such as economic booms or recessions may have long-run effects on later health outcomes. Among the possible mechanisms for this association are diverse factors such as economically influenced changes in nutrition, stress, socioeconomic status, material resources, working conditions, or other factors. Several studies have found effects of economic recessions at different points throughout the life course on later health outcomes, such as economic situation at birth on cardiovascular mortality (Van den Berg et al., 2011) and during working life on older-age cognitive function (Leist et al., 2014).

Closely related to these studies investigating the contextual influences on health differences is the research on successes and failures of social policies in a comparative and longitudinal perspective. In the following, a selection of evidence on the links between social policies and health will be discussed. After that, this article will be closed with pointing to challenges in the translation of evidence into policy changes and practice.

Perspectives on Methodology, Social Policy, and Translation to Practice

Despite all research on social determinants of health, implementing adequate policies to reduce health inequalities is far more difficult than expected. Especially in the U.S., life expectancy drops and morbidity increases despite all knowledge (Berkman, 2009). Not only absolute, but also relative social inequalities persist despite modern welfare regimes, and current theories can only partly explain the pattern of findings (Mackenbach, 2012). Avendano and Kawachi (2014) show that determining the health of a society is a complex question, as multifaceted explanations are needed for the health disadvantages of U.S. Americans compared to people from other high-income countries. Indeed, it is imperative for social epidemiological research today to focus on *social policy assessment* in a context of global social change. Inequality of outcomes in terms of health is certainly one of the strongest challenges of globalizing societies.

Before policy implications can be derived, the search for robust causes of health differences faces a multitude of serious methodological challenges. The introduction and advancement of causal diagrams, i.e., *directed acyclic graphs*, to disentangle causation and correlation in the search for social determinants of health have been valuable to advance our understanding of the pathways through which social factors operate (Glymour, 2006). Social epidemiological research should in the future consider even more than today the role of heterogeneity of effects, i.e., effect modifiers, in determining "what works for whom and when" (Glymour et al., 2013).

These methodological challenges in finding social determinants of health have to be extended in order to determine causation on the macro- and microlevel. In the large domain of causality analysis, further advancements have to be

developed to robustly examine macrolevel causation (Babones, 2008), whereas the panel-based difference-in-differences propensity score matching approach offers a relevant tool to detect microlevel causation (Gebel and Voßemer, 2014). Another relevant example of methodological advancements that social epidemiology should focus on more in the future is to gain evidence if and to which extent social inequalities are caused by effects of age, period, or cohort. The investigation of social times with dynamic analyses and international comparisons are vital tools to detect social policy successes and failures. Then, social epidemiological research has the capacity to robustly detect which societies perform better or worse, how and why, and which social policy changes will work and for which segments of the population in order to improve population health.

Social Epigenetics

Douglas L Anderton, University of South Carolina, Columbia, SC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social epigenetics, the study of social influences on, and outcomes of, changes in gene expression that are not attributable to the basic DNA chain has revolutionized both the role of social science in genetics and the framework for integrating biological influences in social science. Between the genotype and the phenotype lies the epigene, which has now been shown to both be responsive to social influences and result in outcomes of social import. Neurobiological studies have demonstrated the importance of social environments and epigenetic change to developmental disorders. Epidemiological epigenetics has demonstrated the influence of social factors on epigenetic change and the importance of epigenetic changes to health and well-being. A model of inherited genetic influence on social behavior has been replaced with a framework in which genetic influence is altered and mediated by social and environmental factors in producing changes in phenotype of social import. Yet, as great as the promise of social epigenetics is, research confronts both the complexity of the mechanisms involved and what is a new, challenging, research environment for many social scientists.

Social Epigenetics

S*ocial epigenetics* refers to the study of the social influences on, or outcomes of, changes in genetic activity (or gene expression) that are not attributable to the basic DNA chain. For most social and behavioral scientists, social epigenetics requires venturing into unfamiliar territory. The conceptual framework, however, is relatively straightforward. One of the ways in which a gene's expression, or effects, can either change or be suppressed, is through *methylation*, in which a methyl group is added to nucleotides in particular regions of the DNA strand. Thus, methylation may result in a genetic expression, or epigene, that differs from those expected from inherited DNA alone, complicating the association of phenotypes with genetic inheritance. Another source of epigenetic change is *histone modification*, where enzyme-catalyzed changes in the molecular structure of proteins that order the DNA into structural units (nucleosomes) can alter the effective transcription of DNA. Both these sources of epigenetic change affect genetic expression. And, the twist that turns this seemingly biological focus into social epigenetics is simply that both methylation and histone modification, and therefore genetic expression, may be impacted by social behaviors and environments. Modified genetic expression, or the epigene, may then, in turn, affect social consequences or behaviors.

What is particularly interesting then is the interaction between social and genetic influences on gene expression, and the potential impact of this interaction on subsequent genetic expression with social impacts. One often repeated illustration of social and behavioral epigenetics is the effects of stress in methylating regions of the receptor for the stress hormone cortisol, generating gene expression that may subsequently alter the ability to cope with stress. Thus, an essentially social event might result in changes in gene expression that then act similarly to a change in genetics to influence a subsequent social behavior. The last major piece of this framework is the durability of epigenetic changes. Epigenetic changes, just as with DNA, can be transmitted with surprisingly high efficiency (up to 100% for some disease-related changes) from one generation to the next, through meiosis and mitosis during reproduction. So, the effects, for example, of a social exposure or event resulting in methylation can extend across generations along with any health, cognitive, or socially significant effects. At the same time, methylated regions may be chemically demethylated. So, epigenetic effects due to methylation, unlike simple genetic mutation, can be reversed or revert over time and generations. Social epigenetics provides a far more complex, yet intriguing and flexible, framework in which to explore the relationship and interaction of social and genetic expressions.

Foundational and Animal Model Epigenetic Research

The word 'epigenetics' was coined in 1942 but predated any detailed understanding of genetic mechanisms, referring only to the general conceptual model of an interaction between inheritance and the environment. The current usage of the word, referring to changes in gene expression outside fundamental changes in inherited DNA, dates only to the mid-1990s. It is not surprising, then, that much of the research that has raised both prospects of, and expectations for, social epigenetics has been basic research on epigenetics mechanisms and largely derived from animal model research.

Curley et al. (2011) reviewed much of the animal model evidence for social influences and epigenetic effects, especially methylation, during developmental life stages. Authors argue the considerable animal model evidence supports an epigenetic intervening mechanism mediating the relationships of social experiences, gene expression, and neurobiological and behavioral effects. Evidence also suggests, however, the complexity of epigenetic effects with different sensitivity to environmental effects across individuals and sexual dimorphism in effects. And, a similar panel review of behavioral epigenetic evidence (Lester et al., 2011), emphasizing histone modification and primarily relying upon animal model research, reached somewhat similar conclusions and cautions regarding the complexity of epigenetic causal chains within human subjects. Much of this existing animal model research that directly

emphasizes social-behavioral impacts has been of a cognitive nature; how epigenetic changes, usually from *in utero* developmental environments, may alter brain function later in life.

Cognitive and Social Epigenetics

Early emphasis on cognitive epigenetics likely dates from findings near the end of the twentieth century emphasizing the role of methylation, or epigenetics, and parental inheritance in the developmental disorder Angelman syndrome. Research on human subjects and neurobiological or cognitive consequences remain, however, limited. Despite a vast amount of literature on epigenetics, one recent review of the research specifically on behavioral epigenetics found only 96 published articles by 2011 (Lester et al., 2011). Still, some opportunities to extend animal model research on cognitive and behavioral effects have been found. Using brain tissue from suicide victims McGowan et al. (2009), among others, created a quasi-experimental comparison of those with reported childhood abuse and those without. This study replicated their animal model work demonstrating methylation of glucocorticoid receptors, and possible later-life stress-coping effects, among those who had suffered childhood abuse. Miller (2010) summarizes this research and several threads of more recent, specifically cognitive, epigenetic research including changes in gene expression through histone modification that are related to learning and memory, as well as age-related changes in memory. This research has spawned, in turn, the exploration of potential treatments for age-related diseases including Alzheimer's.

Social epigenetics and epidemiological epigenetics have a much wider range of interest than cognitive impacts. These interests extend to the impact of social behaviors and circumstance throughout the life course on epigenetic outcomes ranging from direct health consequences to diffuse effects on subsequent social behavior through both cognitive and other pathways (McGowan et al., 2009; Szyf et al., 2008). Research working from social behavior to epigenetic impact, for example, has explored the plausible effect of diet, stress, isolation, socioeconomic circumstances, etc., on both *in utero* and life-course epigenetic outcomes. Research working from the epigenetic to social, has addressed, for example, the plausible association of epigenetic expression on disease prevalence and health, stress coping behaviors, cognitive disorders or even social expression in deviant behavior. The potential for intergenerational nonrecursive effects, for example, the impact of social disadvantage on potential gene expression reinforcing disadvantage in offspring, has also been one of the most intriguing prospects of social epigenetics for future research. And, unlike the limited availability of biological tissues for cognitive or neurobiological behavioral epigenetics, a large number of human epigenetic studies have used a variety of available human tissues, or other bioassays, to focus on epigenetic epidemiology of specific disease outcomes.

Epidemiological Epigenetics

Much of the epigenetic research considering social influences is concentrated on the role of epigenetic methylation in various cancers and the potential for demethylation as a preventative or active treatment. In much of this work social covariates, for example, diet, socioeconomic resources, environmental exposures, neighborhood effects, and life-course behaviors such as childbearing and rearing, are taken as independent variables related to epigenetic change with disease prevalence as the only social outcome considered. The list of diseases and health conditions of social import that are being studied from an epigenetic framework and using social covariates is large, including many cancers, developmental disorders, obesity, Parkinson's, Alzheimer's, cardiovascular diseases, diabetes, and many more (e.g., Tollefsbol, 2012). The effort to find epigenetic damage linked to both social exposures and disease, i.e., social epigenetic epidemiology, is becoming well established and proceeding rapidly. That is not to say that positive findings in this area of research are yet abundant. However, methods have been developed for a growing variety of biological assays, links of social environment to increased methylation have been demonstrated, and methylation associated with genes of epidemiological importance have been identified (e.g., Oberlander et al., 2008). The paradigm shift has passed and this research is now in a phase of normal science. However, as may be expected, an increasing volume of human epigenetic research is also quickly evidencing more complexity than a simple framework might suggest, and evoking caution if not outright skepticism. Miller (2010) notes that researchers looking at diffuse socioeconomic impacts have not had the success they hoped for, epigenetic effects may be complicated by the fact that effects likely vary by different types of tissues, there is more than one way in which gene expression may be modified, and both individual variability and sexual dimorphism appear to exist in epigenetic susceptibility.

Limitations and Future Social Epigenetic Research

The promise of social epigenetics is evident even to critics, "epigenetics could turn out to be at the heart of some of the most vexing problems in society. These ills include the long-term health problems of people raised in lower socioeconomic environments the vicious cycle in which abused children grow up to be abusive parents and the struggles of drug addicts trying to kick the habit" (Miller, 2010). However, as these critics also note, social epigenetics maybe getting well ahead of itself in the simple fact that much of this speculative value is predicated on the results of animal model research and "there's very little evidence in humans that epigenetics connects early life experience to behavioral or health problems later in life" (Miller, 2010). Moreover, the demonstrated relationships between early life socioeconomic status on gene expression in human populations has not been tied to epigenetic mechanisms as a cause of those observable differences in expression. Much of the work on human populations is still limited to exploratory studies seeking effects on specific health outcomes and not driven by specific hypotheses of any plausible mechanism. In short, to prove the promise of social epigenetics, future research must demonstrate the significance of the mechanism in human populations and relevant to social problems and concerns.

The natural complexity of epigenetic science is also not the only limiting factor to social epigenetic research. For the social and behavioral scientist, this research comes with a new set of demands and research roles that ultimately can only be met by a 'big science' collaborative model of research. Although short-term or even cross-sectional studies can begin to provide critical evidence, the most interesting and definitive studies will certainly require longitudinal data of a very demanding nature. In addition to the obvious needs for bioassays and laboratory work, social epigenetics requires unique statistical skills including, most frequently, large-array methylation analyses and, at the same time, skills in collection of longitudinal social and behavioral data of a detailed nature. Any given study may require a nutritionist, endocrinologist, oncologist, neurologist, psychologist, sociologist, etc., simply to formulate a conceptual framework coherently. Advances will of necessity be collaborative, large scale, multidisciplinary, and costly. This simple reality may ultimately be the most limiting factor on the future progress and promise of social epigenetics.

Social Exclusion, Social Deprivation and Health

Tarani Chandola and Richard Conibere, University of Manchester, Manchester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The literature on social deprivation, social exclusion, and health forms part of the vast body of evidence on the social inequalities in health. People in the most disadvantaged social groups and communities experience a multitude of different types of social exclusion processes such as homelessness, school exclusions, or long-term unemployment, which in turn results in poor health, disease, and disability. The associations between poor health and different dimensions of deprivation, such as income, area, employment, and educational deprivation are well documented. However, there remains some debate about the causal direction of the association. The links between poor health and social exclusion processes such as discrimination, mental illness, homelessness, and asylum seeking are also well documented. Policy responses have tended to focus on lifting the most deprived and excluded individuals out of poverty. However, others have argued on the need for proportionate universalism, which focuses on reducing the steepness of the social gradient in health, through policy actions that are universal, applicable, and appropriate across different social groups.

Concepts and Definitions Related to Social Exclusion and Social Deprivation

The concepts of social deprivation and social exclusion share a similar focus on the inability of individuals to participate fully in the life of their community or society. The measurement of social deprivation has tended to emphasize a lack of material or financial resources that contributes to a lack of social participation, whereas measures of social exclusion have emphasized the lack of participation to a broader range of social, cultural, and political activities (Levitas et al., 2007).

The literature on social deprivation, social exclusion, and health forms part of the vast body of evidence on the social inequalities in health, which incorporates the deprived and excluded groups, as well as other social groups that are relatively better off (CSDH, 2008). People in the most disadvantaged social groups and communities experience a multitude of different types of social exclusion processes such as homelessness, school exclusions, or long-term unemployment. People who are relatively poor but not excluded may experience similar deprivations, such as unemployment or poor living conditions. However their exposure to the range and length of deprivations may be limited compared with those who are socially excluded (Barnes, 2005).

There are a number of different but related dimensions of social deprivation and social exclusion. Some of the key dimensions are discussed below in relation to their associations with health.

Social Deprivation and Health

Income Deprivation, Poverty, and Health

The links between absolute poverty and health are well-known. Those in absolute poverty lack the income to meet basic human needs such as adequate food, water, and shelter. The consequent malnutrition, poor sanitation, and hygiene then tend to lead to higher risks of poverty-originated illnesses and disease. There is some debate about the causal direction: does poverty lead to ill-health or does ill-health cause poverty. However, most commentators agree that the association is likely to be bidirectional (Wagstaff, 2002). The World Health Organization (WHO) has commissioned reports from both perspectives (CSDH, 2008).

Poverty reduction programs tend to focus on the lack of income dimension of poverty and aim to supplement the income of the poor through direct cash transfers or transfer of goods or services in kind. Some of these transfers are 'means tested,' which require the poor to qualify for such transfers on the basis of an eligibility criterion such as having an income below a certain threshold. However, poverty reduction programs often fail to include improving health as a key priority (Bartlett, 2011).

In recent years, one type of poverty reduction program, Conditional Cash Transfer (CCT) programs, have become increasingly popular. The aim is to reduce poverty by making cash or goods transfers conditional upon the recipient's behaviors that are often health promoting, such as getting regular check-ups at the doctor's office, or receiving vaccinations, or the like. A review of conditional cash transfer programs and health (Lagarde et al., 2007) suggests that conditional cash transfer programs are associated with important health improvements such as increased consumption of nutritious food, increased uptake of preventive health services, and decreased incidence of diarrheal disease. However, the review also highlights a number of potential disadvantages to these programs including their cost-effectiveness. Furthermore, such poverty reduction programs typically pay little attention to the structural determinants of health such as increasing access to quality health care and other services, limited interventions in quality or availability of employment, and limited attention to processes that result in social exclusion (Lagarde et al., 2007).

Area Deprivation and Health

The association between area deprivation and poor health has been noted since, at least, the nineteenth century, when stark life expectancy differences between richer and poorer cities were described (Wohl, 1983). Public health reform in the

nineteenth century was mainly concerned with tackling the harmful effects of the physical and social environment, such as the lack of clean water and air, drainage, sewerage, decent housing, education, and regulated working conditions (Fee and Porter, 1992).

Since the 1990s, there has been a renewed interest in the association between area deprivation and health (Macintyre et al., 2008). There has been an extensive literature on the role of compositional (referring to the characteristics of residents) and contextual (referring to the characteristics of the area) determinants of area inequalities in health (Diez-Roux, 1998).

Most studies observe that even after controlling for individual level deprivation, area deprivation remains associated with poorer health and behaviors (Pickett and Pearl, 2001). Rates of ill-health in deprived areas are greater than rates associated with individual level deprivation, even after accounting for individual health risk behaviors such as smoking and drinking. Although compositional factors have the strongest associations with health and health behaviors, contextual factors in terms of where you live also explains some of the association between area deprivation and health. In addition to compositional and contextual factors, collective factors are another type of explanation for area inequalities in health (Macintyre et al., 2008), which emphasizes the importance of shared norms, traditions, values, and interests.

The 'inverse care law' (Tudor Hart, 1971) or 'deprivation amplification' (Macintyre, 2007) are examples of contextual determinants. These concepts describe how people living in deprived areas are also disadvantaged in terms of access to good quality medical services, such as consultation length, referrals to specialist health care, and health promotion clinics, despite having greater need for such services because of the higher rates of illness and disease in those areas. Environmental injustices are a related idea, which suggest that environmental threats to health (e.g., waste disposal sites, and toxic polluting industries) are more likely to be located in deprived areas occupied by the least powerful in society (Hofrichter, 2000).

One of the main critiques of studies on area deprivation and health is that ecological unit ('neighborhood') is portrayed as a 'mystical black box' (Macintyre et al., 2002), failing to capture clear causal pathways between area deprivation and the health outcomes for the residents. Also the ecological fallacy may operate relationships observed between characteristics of area may not necessarily apply to the individuals living in those areas. Additionally there is the question of scale – do the administrative units of convenience such as census tracts, wards, and output areas really represent a neighborhood or context to which residents identify and belong. Related to this is the Modifiable Areal Unit Problem where conclusions of studies can change according to the arbitrary set of boundaries used (Holt et al., 1996).

Employment Deprivation/Long-Term Unemployment and Health

Unemployment is generally associated with poorer health and lower well-being. A *metaanalysis* of 42 longitudinal studies found that the unemployment is associated with a 63% increased mortality risk than the population as a whole (Roelfs et al., 2011). Furthermore, long-term unemployment is associated with poorer health than short-term unemployment (Nichols et al., 2013). Long-term joblessness could also result in higher mortality (Couch et al., 2013).

There is a long history of research showing that becoming unemployed has large negative effects on mental health, but the evidence on long-term unemployment and worsening mental health is more mixed. There is at least a twofold increased risk of mental health problems among the long-term unemployed, particularly depression and anxiety disorders, compared with the employed (Herbig et al., 2013; Paul and Moser, 2009; Brown et al., 2003). Higher rates of long-term unemployment are associated with increased suicide rates, (Classen and Dunn, 2012), alcohol-related disease, mental illness, and suicide attempts (Browning and Heinesen, 2012). However, there is also some evidence that a longer duration of unemployment is positively correlated with well-being, conditional on being unemployed (Clark and Oswald, 1994).

The mechanism for this increase in risk of mortality and mental health problems is unclear but could be related to income loss, increases in risky health behavior (Browning and Heinesen, 2012), and losses of health insurance coverage (Olson, 1992). In addition, when individuals are out of work for long periods, their skills tend to decline through lack of use, with negative consequences for finding reemployment and potential wages once they find a job. Similarly, being out of work potentially reduces a worker's network of business or social contacts that enables access to jobs. Furthermore, household income decreases during unemployment, and the loss in income becomes larger with longer durations of unemployment. Although most welfare states have some form of unemployment welfare payments, replacement income is often lower than the minimum income needed for healthy living (Morris et al., 2000). In addition, the long-term unemployed may suffer from the stress of being out of work and having to look for work. Lower incomes during long periods of unemployment can affect a person's and their family's well-being. Long-term unemployment within communities could also negatively affect the provision and quality of public services (Nichols et al., 2013).

Despite these plausible mechanisms linking longer periods of unemployment to poorer health, there is considerable debate over the direction of causality. This is because of selection processes in which workers with poor health or disabilities are more likely to become unemployed and less likely to be reemployed. The long-term unemployed may have underlying health problems that result in becoming unemployed. For example, workers with disabilities or mental health problems are more likely to lose their jobs during periods of economic downturns than other, more able bodied workers (Schneider, 2011). While bidirectional causal associations may exist between long-term unemployment and poor health, it is difficult to isolate and estimate the effects from any one direction.

Educational Deprivation/Lack of Qualifications and Health

Childhood deprivation, educational attainment, and later-life outcomes in adulthood are closely linked (DCSF, 2009). Childhood deprivation has a negative impact on educational attainment resulting in increased risk of a child leaving full

time education without any qualifications or skills. Such educational deprivation has indirect and direct consequences on well-being. There may be direct effects on employment and earnings, as people without any qualifications find it harder to find jobs, particularly skilled jobs. The effects of employment deprivation on health have been discussed in the previous section. In addition, lower skilled people are more likely to find employment in physically dangerous occupations, or poorly regulated work with increased risks of accidents (Feinstein et al., 2006). Educational deprivation may also be indirectly associated with lower well-being through effects on health behaviors. Low levels of education may result in a poor understanding the risks associated with risky behaviors such as smoking or drug use (Cutler and Lleras-Muney, 2010). The association between lack of education and low access to quality health care services is also very strong (Cutler and Lleras-Muney, 2010).

Literacy is one of the key skills acquired in basic education (Rajan et al., 2013). Literacy predicts good health in both developed and developing countries (De Walt et al., 2004; Kabir, 2008; CSDH, 2008) and enables a person to engage with the healthcare services and respond to public health campaigns (De Walt et al., 2004: 1232). In poor countries, female illiteracy in particular, is associated with poor health outcomes such as maternal and child mortality (Caldwell, 1986: 184–187; Sen, 1999: 195–198).

Social Exclusion and Health

The concepts of social exclusion and poverty are also highly interrelated. The concept of social exclusion emerged largely in reaction to a narrow definition of poverty largely concerned with income and consumption (Levitas et al., 2007). Poverty can be conceptualized in terms of material as well as social deprivation, whilst social exclusion emphasizes both a person's or a group's inability to participate in social, economic, political, and cultural life and also their relationships with others. And while poverty has a profound effect on some, though not all, of these aspects of social exclusion, there are other important causal factors of social exclusion such as age, disability, ethnicity, gender, and employment status.

Most of the research on social exclusion and health tends to focus on specific aspects of social life that people are excluded from (e.g., income, employment) or particular excluded groups (e.g., the homeless, refugees, specific ethnic, or racial groups). This implicitly conceptualizes social exclusion as a state, rather than a process.

There are many dimensions of social exclusion such as from economic productive processes like employment, good-quality education, living and working conditions, political participation, and cultural resources that can result in social exclusion. Each of these processes can combine and reinforce each other across a person's life course to produce varying degrees of vulnerability and social exclusion.

Discrimination

Discrimination is a key dimension of social exclusion and is also a key cause of health inequity. Discrimination results in unequal access to health services, as well as unequal access to the underlying (social) determinants of health like access to safe water, sanitation, and adequate housing and nutrition.

Direct discrimination occurs when key gatekeepers for services discriminate against the socially excluded. An example is when doctors or health care workers give poorer quality care to the illiterate, the disadvantaged, or the unempowered. This can be manifested through longer waiting times, inadequate diagnosis, the provision of less quality medication, patient segregation, or neglect in patient hygiene or nutrition. Indirect discrimination can manifest, for example, when access to information on health services is typically provided only in the language of the dominant ethnic or racial group or in accordance with dominant cultural practices.

Ethnic minorities and indigenous peoples are often subject to direct and indirect forms of discrimination. Disproportionately high rates of poverty and low rate of employment (or underemployment) among the socially excluded affect their chances of health. They are typically pushed into low-skilled jobs with higher occupational health risks, living in inadequate housing and have less food security. They tend to be poorer than other social groups, making it harder for them to access private health services. Direct and indirect forms of discrimination can interact and result in greater social exclusion. For example, poor, uneducated migrants are at greater risk of exclusion than rich, skilled migrants. Groups such as Roma, migrants, people with disabilities and the very old become particularly vulnerable when they experience multiple exclusionary processes and the social exclusion and discriminatory processes become entrenched (Popay et al., 2008).

Gender discrimination also remains a key health issue, highlighted by the poor state of women's reproductive health rights among socially excluded groups. There is evidence from around the world to show that women from marginalized minorities and indigenous peoples have disproportionately high rates of maternal mortality and often have less access to reproductive health services (MRGI, 2013). In some severe cases, minority women can be coerced or intimidated into making involuntary decisions regarding their sexual and reproductive health, such as sterilization or abortion.

Exclusion from Services and Health/Inverse Care Law

The inverse care law states that "the availability of good medical care tends to vary inversely with the need for it in the population served" (Tudor Hart, 1971). Access to services is also affected by the inverse care law. Those with the greatest need for healthcare use the services the least. The 'Inverse Care Law' has also been used to describe how socially excluded groups are also disadvantaged in terms of access, consultation length, quality of service, likelihood of diagnosis, referrals to specialists or secondary and tertiary services, waiting time, health promotion clinics, and patient enablement processes.

Exclusion due to Disability

Around 15% of the world's population, or estimated 1 billion people, live with disabilities (WHO, 2011). They are the world's largest minority. This figure is increasing through population growth, medical advances, and the aging process,

says the World Health Organization (WHO). In countries with life expectancies over 70 years, individuals spend on average about 8 years, or 11.5% of their life span, living with disabilities.

Persons with disabilities differ in the type and severity of disability, which in turn impacts on their health and well-being. Furthermore, other social determinants of health, such as gender, socioeconomic status, race, and ethnicity, interact with the types of disability and influences how people with disabilities access health care (Sullivan et al., 2006; Alborz et al., 2005). Evidence suggests that persons with disabilities, in general, are more likely than able-bodied counterparts to have multiple and complex health care needs; to perceive their health status as poor; to report having unmet health care needs; and to have lower levels of satisfaction with health care (AHS, 2008).

People with disabilities in developing countries are overrepresented among the poorest people. However, poverty reduction strategies in poor countries have often overlooked the disabled (Miller and Ziegler, 2006). In the developed world, welfare care systems take account of people with disabilities with varying degrees of success. The community model of health care largely operates with most people with disabilities living in the community. This has resulted in people with disabilities becoming more reliant on key gatekeepers to services such as general practitioners to meet their care needs (Caldas de Almeida and Killaspy, 2011). However, these gatekeepers may lack experience and specialized knowledge of complex disabling conditions, or may engender social exclusionary processes through conscious or unconscious discriminatory practices (Parish and Saville, 2006; Ruddick, 2005). The community model of care has also increased care burden stress among the informal carers of people with disabilities, particularly family members and friends (Ouelette-Kuntz et al., 2005).

Exclusion due to Mental Illness

People with mental illness tend to be overrepresented in all socially excluded groups. There is a strong link between mental illness and deprivation, with the proportion of mental health problems being much higher in disadvantaged social groups such as those classified as being in poverty, the homeless, the unemployed, minority ethnic groups, and combinations of these categories (Bonner et al., 2002). People with mental health problems are often socially excluded as a result of social stigma. Such direct discrimination can result in limited social capital, resulting in further social exclusion.

Mental health problems can cause homelessness and can also result in homelessness (Morgan et al., 2007). People with mental health problems may lose secure sources of income which makes it difficult for them to sustain their tenancies. On the other hand, the experience of homelessness is extremely isolating and can engender feelings of powerlessness and hopelessness, which in turn can cause or exacerbate mental health conditions.

Exclusion due to Homelessness

Homelessness is a significant public health concern in the developed and developing world. Access to shelter is a basic human need, so the strong association with poor health is not surprising. Homeless people without any shelter ('rough sleepers') in particular have especially poor health outcomes, and their life expectancy is much lower than the general population (Hwang et al., 2009). However, there are other manifestations of homelessness, such as staying in overcrowded, temporary, or inadequate accommodation which in turn can have a damaging effect on a physical and mental health. These include problems related to respiratory conditions, infectious diseases such as tuberculosis and sexually transmitted infections, drug and alcohol problems. Cohabitation in overcrowded homeless shelters or inadequate housing increases the risk of airborne infections, such as tuberculosis. Social isolation as a result of homelessness results in the loss of social support, which in turn is associated with low compliance with medication (Galea and Vlahov, 2002). Homelessness can also limit a person's access to adequate health or social services, as access may depend on residency in a particular area or city.

Exclusion due to Asylum Seeker or Refugee Status

Refugees and Asylum seekers differ from other groups of immigrants in key characteristics. They are more likely to have been exposed to war, violence, and torture, having experienced forced migration and exile, as well as insecurity in terms of their status in the countries where they seek refuge. Most studies on immigrants find some evidence of the 'healthy immigrant effect' – the health of immigrants tends to be better than that of the general population in both the sending and receiving countries. This effect reflects the selection processes that immigrants face when migrating; immigrants with poor health are less likely to overcome some of the social, economic, and political barriers to migration. In contrast to the general finding of healthy migrant effects, there is evidence that refugee and asylum seekers are at substantially higher risk than the general population for a variety of specific psychiatric disorders (Coid et al., 2008; Jarvis, 2007). For example, those exposed to torture are highly likely to experience symptoms of post-traumatic stress disorder (Steel et al., 2009).

Explanations for this increased risk in psychiatric disorders lie partly in the disruptions to the social support and networks of refugees and asylum seekers when they migrate. Furthermore, during migration, many refugees experience prolonged uncertainty about their citizenship status (Kirmayer et al., 2011). In some countries, harsh conditions in detention centers can lead to a sense of hopelessness among asylum seekers (Silove et al., 2007).

Criticisms of Social Exclusion

The concept of social exclusion has been criticized for being "a broad screen, a curtain, which [hides] problems of desperate destitution" (Gore and Figueiredo, 1997: 44) irrelevant to regions and countries where a majority of people are experiencing severe poverty. This approach suggests that the policy focus should be on alleviating poverty rather than on inclusionary policies. However, as Sen argues (2000: 6) "the real importance of the idea of social exclusion lies in emphasizing the role of relational features in the deprivation of capability"

and thus highlighting the causal relationship between poverty and wider inequalities in societies.

There is some debate over the measurement of social exclusion. Some studies use a series of markers of social disadvantage and differentiation (e.g., social class, employment status, contact with the legal system) to demarcate social exclusion. However, this approach ignores the concept of social exclusion as a process and the importance of agency (Perkins and Repper, 2003). Parr et al. (2004) conceptualizes exclusion and inclusion as subjective states of belonging and involvement in local communities determined by the actions of others in the immediate social milieu. Individuals, in this account, feel more or less included at different times; being excluded is not a static fixed state that can be objectively measured, but a fluid process. This implies a very different approach to studying social exclusion from that used in most studies of social exclusion and health to date.

Policy Responses

The socially deprived tend to have higher levels of ill health compared with more advantaged groups, resulting in a social gradient in health that increases with levels and durations of deprivation (CSDH, 2008). There are marked differences in health between social classes, occupational hierarchies, and status-related social groups. Policy responses to this link between socioeconomic circumstances and health have tended to focus on those in the poorest circumstances and the poorest health, on the most socially excluded, those with most risk factors, and those most difficult to reach (Graham and Kelly, 2004). This is a policy approach that attempts to lift the worst off out of extreme poverty. However, such interventions are likely to help only a relatively small part of the population as those in extreme poverty only constitute a small part of the population (Graham and Kelly, 2004).

Another approach recognizes that the link between social deprivation and health is part of a broader social gradient in health. There are large numbers of people who, while they could not be described as socially excluded, are relatively disadvantaged in health terms. Focusing solely on the most deprived or excluded will not reduce health inequalities sufficiently for this broader group of the population. To reduce the steepness of the social gradient in health, policy actions must be universal and applicable across different social groups. However, the scale and intensity of such policy actions should be proportionate to the level of deprivation and social exclusions. Such policy actions have been termed proportionate universalism (Marmot, 2010).

Abstract

This article provides the foundation for understanding social experiments and why it is valuable to conduct them. (For a more detailed discussion of most of the topics included in this article, see Orr (1999).) It begins by defining the term and discussing the rationale for using experimental methods to evaluate social policies, practices, and programs. It then discusses the design and analysis of social experiments, and the issues of internal and external validity of social experiments. The article concludes with a brief discussion of the ethics of such studies and an historical perspective on social experimentation.

What Is a Social Experiment?

A social experiment is a field trial of a policy, practice, program, or other social intervention in which participants are randomly assigned to different 'treatments' or experimental conditions. An experiment may include multiple interventions, or 'treatment groups,' and usually, though not always, a 'control group,' which receives no special treatment. The control group represents the 'counterfactual,' or what would have happened to the treatment group in the absence of the treatment. Therefore, comparing the mean postrandom assignment outcomes of a treatment group with those of the control group yields a measure of the 'impact' of that intervention relative to what the controls would have experienced in the absence of the intervention.

For example, an experiment designed to test two different types of job search assistance (JSA) might randomly assign job-seekers to three groups: a group that receives JSA Type 1 (JSA1), a group that receives JSA Type 2 (JSA2), and a control group, which receives no special assistance. The effect of JSA1 relative to no assistance – its 'net impact' – would be measured by the difference in mean postrandom assignment employment and earnings between the JSA1 group and the control group. Similarly, the effect of JSA2 relative to no assistance would be measured by the difference in mean employment and earnings between the JSA2 group and the control group. The 'differential impact' of JSA1 relative to JSA2 would be measured by the difference in mean outcomes between the two intervention groups. Net impact estimates answer the question, what effect would adopting the intervention have relative to not adopting the program? Differential impacts answer the question, which type of intervention is more effective? In the following section, we elaborate on these ideas and show why social experiments with random assignment have become the 'gold standard' of program evaluation.

Why Experiment?

In popular parlance, 'experimenting' is usually taken to mean implementing a new program, policy, or practice (also referred to throughout this section as *a strategy* or *intervention*) on a small scale to see if it works. If the intervention is truly new, then only by setting up a pilot test is it possible to obtain empirical evidence of its effects. One rationale for social experiments, then, is to create a working model of the intervention so that it can be evaluated. However, determining whether the strategy works requires much more than simply observing it in action.

To see why, it is useful to consider what we mean when we say that a strategy does or does not 'work' and what ways we have of making that determination. We take the question of whether a strategy works to mean whether it is effective in achieving its goals. For most programs, those goals have to do with the effects of the program on its intended beneficiaries. Some interventions have a single goal; others have multiple goals. For example, the goal of a job training program is to increase the earnings of the trainees, whereas a community service program might have multiple objectives, such as providing valuable services to the community, encouraging out-of-school youths to obtain a General Educational Development (GED) certificate, and reducing their antisocial behavior. The behaviors and circumstances of those who are the targets of the intervention under study any time after they are first exposed to the intervention are termed 'outcomes'. (Because some effects can occur almost immediately, while the participant is still in the in the program under study, we define outcomes to include everything that happens after random assignment, not just what happens after the participant leaves the program.) To determine whether the strategy being tested works, we must determine whether it succeeded in changing the outcomes it was intended to affect.

One can, of course, observe the outcomes of interest – for example, postprogram earnings of trainees or GED completion rate of service corps members – simply by following individuals during and after the time when they are exposed to the intervention. But one cannot, on the basis of the observed behavior alone, know what portion of the observed post-program outcomes should be attributed to the intervention. We define the '*impact*' of a program, policy, or practice under study as the difference between the observed outcomes for those subjected to the intervention condition (for example, their postprogram earnings) and *what those outcomes would have been in the absence of the intervention under study*.

Suppose, for example, that 80% of the participants in a job training program obtain jobs within a year of entering the

program. Does that mean that the program is achieving its objective of securing employment for unemployed workers? Not necessarily. Some of the trainees would have found jobs even if they had not participated in the program. If only 20% would have found jobs in the absence of the program, then the program increased the participants' employment rate by 60 percentage points. However, if 80% of those in the program would have found work on their own in the absence of the program, then the program has had no impact on their employment rate. (Of course, in the latter case, the program might have helped them get better jobs, and conceivably it could improve their long-term employment and earnings. Thus, it would be useful also to consider impacts on earnings and possible longer-term outcomes in addition to the 1-year employment rate.)

Similar reasoning applies to other programs, policies, and practices and their outcomes and objectives. Identifying the impacts of particular strategies requires being able to measure the outcomes for those who experienced the particular strategy under study and being able to compare them with what those outcomes would have been had those same individuals *not* experienced the intervention. We can only attribute behavioral changes over and above that base level to the intervention. The fundamental problem of program evaluation, then, is to determine what would have happened in the absence of the intervention. Measuring the actual outcomes of participants is relatively straightforward; not surprisingly, measuring what they would have done in the absence of the intervention under study is much more difficult.

There are, however, a number of different ways to attempt to *estimate* what would have happened to the participants in the absence of the intervention, which we term the *counterfactual* condition. To understand why experimental methods are the preferred approach for estimating what would have happened in the absence of the intervention, it is useful to understand the shortcomings of other approaches. Therefore, we briefly discuss the two principal alternatives to experimental designs: (1) *pre–post designs*, which are also called *reflexive* designs or *one-group pretest–posttest designs* (Campbell and Stanley, 1963, pp. 6–13) and (2) *comparison group designs*, sometimes called *static-group comparison designs* or *double-difference designs*. These designs are two of the most intuitive and common ways to think about whether a particular intervention improves outcomes in the intended ways. (These two broad approaches subsume a large number of specific statistical impact estimation methods. For example, pre–post designs include 'interrupted time series' methods that estimate impacts on the basis of postintervention departures from the preintervention *trend* in the outcome, and comparison groups can be formed through a variety of selection and/or matching procedures. The fundamental characteristics, advantages, and disadvantages of these approaches discussed here apply to all of these more specific estimation methods.)

Pre–Post Designs

A particularly simple way to attempt to determine what would have happened in the absence of the intervention under study is to use the behavior of the participants before they experienced the intervention as a predictor of what their outcomes would have been had they not been exposed to the experimental intervention. In the case of a social development program for young children, for example, we might use the participants' social competence scores in the year before they entered the program as an indicator of what their outcomes would have been in the absence of the program. We would then measure the impact of the program as the change in social competence scores between the year prior to program participation and the year after it. This design has the advantage of requiring data only on the individuals who participated in the program under study.

Importantly, pre–post designs are not always feasible and, even when they are, they have substantial limitations. The outcome of interest might not be defined in the preprogram period. For example, pre–post designs could not be used to estimate the effect of a maternal health program for pregnant women on infant birth weight, which can only be measured after the intervention has been delivered. More importantly, even where preprogram data can be collected, for several reasons behavior in the period prior to exposure to the intervention may not be a good predictor of what would have happened later, in the absence of the intervention.

Environmental factors external to the program that affect the outcomes of interest might change over the time period between the pre- and postmeasures. In the case of a dropout-prevention program, for example, deterioration of job opportunities in the local economy might result in fewer students dropping out of school to go to work, quite aside from any effect of the program. In this case, a pre–post impact measure would erroneously attribute this improvement in school retention to the program rather than to changes in the opportunity cost of attending school.

Of particular importance to interventions focused on children, outcomes may also change over time because of natural *maturation processes*. Consider, for example, the social development program mentioned above, in which preprogram social competence scores are used to estimate the postprogram counterfactual. Even without a special program, children's social skills can be expected to improve over time, e.g., through interaction with parents and siblings at home. Thus, the pre–post impact measure would overstate the effects of the program by including in that measure of program impact those gains in skills that would have occurred anyway.

Even when there are no environmental factors or maturation effects that render pre–post measures poor indicators of the impacts of an intervention, pre–post designs can yield misleading conclusions if, on average, the preprogram period was atypical for subjects exposed to the intervention. Consider, for example, job training programs for workers who have lost their jobs. Even without the program's assistance, many of these workers would have found jobs on their own. Thus, even without the program, some program participants would show improved performance from the period before to the period after program entry. Statisticians refer to this as *regression to the mean*. A pre–post evaluation would attribute these gains in employment to the training program. (This type of effect is most pronounced when program participants are drawn disproportionately from one extreme of the performance distribution, in this case the lower end.)

This phenomenon of individuals participating in programs when their outcomes of interest are at atypical levels is fairly general. Social interventions are often targeted at individuals based on indicators of need that are similar to those that will be the basis for judging the effectiveness of the intervention (for example, health, earnings, or academic performance). To the extent that these needs would be only temporary even without the intervention, selection on need will result in regression to the mean, with need greatest around the time of program entry, then falling over time. In such cases, simple pre–post differences in outcomes will overstate the effect of the program by including the rebound from this temporary period of need, which would have occurred even without the program's help.

Figures 1 and 2 illustrate how reliance on the outcomes of intervention participants alone can create a misleading impression of the effectiveness of an intervention.

Figure 1 shows the time path of welfare benefits received by participants in the Child Assistance Program, a welfare-to-work demonstration (Hamilton et al., 1998). The steep, continuous drop in welfare benefits over a 5-year period would appear to indicate that the program was quite effective in achieving its objective of moving assistance recipients from welfare to employment. This is in fact the type of 'evidence' that is frequently used to demonstrate program effectiveness in the legislative process and in the popular media.

Figure 1 Welfare benefits of participants in a welfare-to-work program.

Figure 2 Welfare benefits of participants in a welfare-to-work program and a randomly assigned control group excluded from the program.

As shown in Figure 2, however, a control group of program eligibles who were *excluded* from the program on the basis of a lottery, as part of a social experiment, experienced essentially the same decline in welfare benefits over the same period. This comparison demonstrates that most of the reduction in benefits received by program participants was not attributable to the program, but to the natural process of caseload turnover, as women leave welfare when they find employment or another source of support (e.g., a working partner or spouse or parent), or their children age out of eligibility.

Comparison Group Designs

As the previous example suggests, one way to avoid some of the hazards of pre–post designs is through the use of a comparison group – a group of individuals who are as similar as possible to those selected to experience the intervention under study, except that they are not exposed to the intervention. Under this strategy, the pre–post change in outcomes of the comparison group is used to represent what would have happened to those in the intervention group had they not been exposed to the program, policy, or practice under study.

Ideally, the pre–post change in outcomes of the comparison group will reflect any environmental factors, natural maturation effects, and rebound from atypical behavior or circumstances that affect the outcomes. If that is true, subtracting the pre–post change in outcomes of the comparison group from the pre–post change in outcomes of the intervention group should eliminate these nonintervention factors and yield a more accurate measure of the impact of the program, policy, or practice under study. This is sometimes called the *double-difference* model or, in the language of Campbell and Stanley (1963, pp. 47–50), the nonequivalent comparison group model.

Table 1 illustrates this approach using data from the evaluation of the Job Training Partnership Act program, a national training and job placement program for disadvantaged workers (Orr et al., 1996). The outcome of interest, quarterly earnings, was measured for participants in the quarters before program entry and 18 months later. The first row of the able shows that a simple pre–post measure of impact, using data for participants only, would indicate that the program increased earnings by $281, from $400 per quarter to $681. The second row shows the change in earnings of a sample of low-wage workers who did not apply to the program. Suppose we use that sample as a comparison group. Under the assumption that *in the absence of the program* JTPA participants would have experienced the same increase in earnings as the nonparticipant sample, the comparison group approach estimates the impact of the program as $136 – the change in average earnings from pre- to post-program for the JTPA participant group less the pre–post change for the comparison group (see row three).

The comparison group design thus avoids the erroneous attribution of the full increase in earnings that results pre–post

Table 1 Estimating the impact of JTPA with a comparison group design

Group	*Preprogram earnings*	*Earnings 18 months after program entry*	*Pre–post change*
1. Treatment group (JTPA participants)	$400	$681	$281
2. Comparison group	$1050	$1195	$145
3. Estimated impact (difference in differences)	–	–	$136

to the program in question. Rather, only the change above and beyond that experienced by the comparison group is attributed to the intervention.

Importantly, it is still possible, however, that the net difference in outcomes will not be a fair estimate of the impact of the intervention; the measure is potentially biased due to the way the intervention and comparison groups were selected. Because the pervasiveness of 'selection bias' in nonexperimental comparison group designs is one of the most important reasons for preferring experimental methods, we now examine this phenomenon in more detail. We then return to the estimation of JTPA impacts in light of that discussion.

Selection Bias

The comparison group design is based on the assumption that those in the intervention group would have experienced the same change in outcomes as the comparison group had they not been subject to the intervention being studied. Estimates based on comparison group designs are only as valid as this assumption. Ultimately, one can never be sure how valid that assumption is because it is a statement about something that is inherently unobservable – the experience of the intervention or treatment group if they had not experienced the intervention.

What we do know is that the intervention group is either self-selected or selected by somebody else (for example, students might be selected by teachers) to experience the intervention, whereas the comparison group members were not selected in the same way. Unless those selection decisions are identical for both groups, the two groups may well differ in ways that may or may not be observable. If the difference(s) that led one group to be selected for the intervention and the other not to be selected also lead to differences in the outcomes of interest, the comparison group design will erroneously attribute to the intervention those differences in outcomes that are really due to differences in who was selected for the respective groups. Such errors in attribution are termed *selection bias*.

One can, of course, attempt to match the comparison group to the participants in terms of such personal characteristics as age, race, gender, ethnicity, prior earnings, etc. However, if the two groups differ in *unmeasured* characteristics, such as motivation, native ability, or family and community resources, their outcomes might differ for reasons that have nothing to do with the intervention under study. However, even when the two groups are matched on measured characteristics, selection bias can occur based on those characteristics if the measured status of one group is temporary and that of the other is permanent. Suppose, for example, participants in the JTPA program are matched to a sample of workers in the general population with similar recent employment and earnings. If the trainees applied to the program because they had recently lost their jobs, their low earnings are likely to be temporary, whereas workers in the general population with similar earnings are likely to have permanently low earnings. When the trainees' earnings rebound from their temporarily low levels, it will appear that the program substantially increased their earnings. (This well-known phenomenon, termed the 'preprogram dip' in the job training literature, was first known as the 'preprogram dip,' was first noted by Ashenfelter (1978).) In fact, if the impact of JTPA on quarterly earnings at 18 months after program entry is estimated with a randomly assigned control group rather than a nonexperimental comparison group, it is found to be $53, rather than the $136 shown in **Table 1**. (This estimate is provided for illustrative purposes only; the actual impact estimates in the JTPA evaluation were derived by a more complex regression-based procedure (see Orr et al., 1996).)

The Rationale for Experimental Designs

Random assignment offers a way to create a comparison group that is not systematically different from the group subject to the intervention under study – that is, one that is not subject to selection bias. If assignment to the intervention group or to the comparison group is completely random, selection into one group or the other is *by definition* unrelated to any characteristics of the individual and, therefore, to the outcomes expected in the absence of the intervention. When individuals have been randomly assigned to the experimental conditions, any systematic differences in postrandom assignment outcomes between the groups can confidently be attributed to the interventions, if any, that individuals in the groups received. (By *systematic* differences, we mean any differences that are larger than might be expected on the basis of sampling error. Below, we discuss how one can test whether the between-group difference is likely to be due to sampling error.)

The defining characteristic of a *social experiment* is that it entails random assignment of some pool of individuals (or clusters of individuals such as whole schools or classrooms) to two or more groups that are subject to different program, policy, or practice regimes. Typically, one of these groups is a *control group* that is subject to prevailing, 'business-as-usual' conditions (that is, it is excluded from the experimental intervention). (Experimental control groups are a special type of comparison group. For clarity we will use the term 'comparison group' to mean a nonexperimental comparison group and we use the term 'control group' to denote a comparison group created through random assignment. Occasionally, a social experiment does not include a control group subject to the prevailing conditions, but rather consists of two or more groups created through random assignment that receive different interventions.) In addition, one or more *intervention groups* consist of individuals or clusters of individuals who are assigned to

the intervention being studied. The relevant outcomes of each group are then measured over some follow-up period and the impact of the intervention is estimated as the difference in outcomes between intervention and control groups. Because random assignment assures that exposure to the intervention under study is the only *systematic* difference between the treatment and control groups, the observed difference in subsequent outcomes between those in the intervention and the control groups will be free of selection bias; the difference in means between the two groups will be an unbiased estimate of the impact of the intervention.

By *random assignment* we mean assignment to groups on the basis of a random event, such that (1) the outcome of assignment is unpredictable, and (2) each individual or cluster has a specified probability of being assigned to each group. (Random assignment does *not* simply mean haphazard or arbitrary assignment. In practice, great care must be taken to ensure that each individual or cluster assigned has the prescribed probability of assignment to each group.) The random event can be as simple as the flip of a coin – if the coin comes up heads, the individual is assigned to the treatment group; if it comes up tails, the individual is assigned to the control group. In this example, each individual has a 50% chance of assignment to each group; if large numbers of individuals are randomly assigned, the total sample will be divided approximately evenly between the treatment and control groups, and the groups will have statistically similar characteristics.

In practice, random assignment is usually based on specially designed tables of random numbers or computer algorithms that generate random numbers. In most cases, the unit of randomization (individual or cluster) should be the same as the unit to which the intervention under study pertains. For example, in a study of supplemental education services intended for students with particular needs, individual students would usually be assigned to the intervention or control condition, whereas if the intervention were a new math curriculum, it would be appropriate to randomly assign classrooms. (Special statistical considerations pertain to situations in which clusters of individuals (such as classrooms) are assigned to treatment or control conditions.)

Suppose, for example, that we wish to evaluate an education voucher program such as the one that was implemented and studied in Washington, DC (Wolf et al., 2008). We might begin by setting up the program on a pilot basis and recruiting applicants. Those judged eligible (and still interested after learning more about the program) would then be randomly assigned to an intervention group, which would receive vouchers that could be used to pay for private school tuition, or to a control group, which would not receive vouchers. Over the next several years, we would collect data for both groups on outcomes that might be expected to be affected by receipt of the voucher, such as academic performance of students, parents' and students' perceptions of school safety, and overall satisfaction with the school. The impact of the program on each of these outcomes would be measured by the difference in means between the intervention and control groups over the follow-up period.

Through random assignment, the two groups would be well matched at the point of entry into the program. Therefore, in this example, it is not essential to compare the *changes* in the two groups' outcomes over the follow-up period, as we did in the comparison group design described above. The simple intervention-control difference in postrandom assignment outcomes will, on average, give the same answer as the intervention-control difference in *changes* in outcomes pre-to post-random assignment, because there will be no systematic difference between the two groups at the point of random assignment. Taking the preprogram value of the outcome variable into account will, however, improve the quality or *precision* of the impact estimates.

Although this simple example illustrates the fundamental elements of a social experiment, the range of possible variations on this basic theme is enormous. For example, instead of evaluating a single program, one might wish to compare several different program models or estimate the effects of specific program components. Alternatively, instead of simply estimating the impacts of a particular school voucher program, one might want to study the impacts of programs that offer high and low voucher amounts. Or, instead of studying the effects of the program on applicants who voluntarily apply to the school voucher program, one might wish to study the effects of the program on the entire population eligible for the program in order to see who among those eligible use the vouchers, as well as estimate the average impact across all eligible students.

Designing a Social Experiment

The experimental design consists of specification of the experimental conditions to which subjects are to be randomly assigned and the numbers to be assigned to each condition. The choice of experimental conditions is driven by the policy question to be answered. If a single intervention (new or existing) is to be evaluated, the design will normally consist of a single treatment group, which receives that intervention, and a control group that does not. Testing multiple interventions requires multiple treatment groups, although a single control group will normally suffice as the counterfactual for each treatment group. Impact estimates based on comparison of a treatment group and the control group are termed *net impacts*; they measure the effect of the experimental intervention relative to the status quo. Comparison of the outcomes of one intervention to those of another yields *differential impacts*, the impact of one intervention relative to another. The ability to use a single control group for multiple interventions and the ability to estimate differential impacts are strong reasons to include multiple interventions in the same experiment whenever multiple interventions are relevant for policy.

The proportions of sample assigned to different experimental conditions will affect the precision with which different impacts are measured – i.e., the standard error of the estimate. In general, the smaller the experimental groups being compared, the less precise will be the estimate (i.e., the larger its standard error). Equal allocation to each group will provide equally precise estimates of the net and differential impacts of each intervention tested.

The absolute precision of the estimates will depend not just on the proportional allocation of the sample but on the absolute number of subjects assigned to each experimental condition. For each impact of interest, one can – and

should – compute *ex ante* the *minimum detectable effect, or MDE* – the smallest true effect that can be detected by the design at a specified level of statistical significance and statistical power. ('Statistical significance' measures the risk of concluding that the intervention had an effect when it did not, sometimes termed a Type 1 error. For example, testing impacts at the 0.05 significance level entails a 5% risk of accepting as real a treatment-control difference that occurred by chance, as a result of random assignment. 'Power' measures the likelihood that the design will detect a true effect of a given size. For example, 80% power to detect a $100 increase in earnings means that if the *true* effect of the intervention is to raise earnings by $100, then in repeated sampling and random assignment, we would detect a statistically significant effect 80% of the time.) Small MDEs help assure that impacts that would be relevant for policy are not missed by the experiment just because the sample is too small to detect them. A simplified formula for the MDE is

$$\begin{aligned}\mathrm{MDE} &= k(\alpha, B)\mathrm{SEE}(\widehat{\beta}) \\ &= k(\alpha, B)\sqrt{\frac{\sigma_Y^2}{n_\mathrm{T}} + \frac{\sigma_Y^2}{n_\mathrm{C}}}\end{aligned}$$

where

α = significance level
B = power
$\widehat{\beta}$ = estimated impact
$\mathrm{SEE}(\widehat{\beta})$ = standard error of the impact estimate
σ_Y^2 = variance of outcome Y
n_T, n_C = sample size of treatment and control groups

As can be seen from the formula, the MDE depends critically on the variance of the outcome and the sample sizes of the two groups being compared (in this case, a treatment group and a control group, although it could equally well be two treatment groups). Lower variance outcomes and larger sample sizes yield smaller (more precise) MDEs. The multiplicative factor $k(\alpha, B)$ is a complex function of the significance level (α) and power (B) chosen by the researcher. Lower levels of power (e.g., 70% rather than 80%) reduce the MDE – but at the cost of a higher risk of missing a true effect. Lower levels of significance (e.g., the 0.10 level rather than the 0.05 level) also reduce the MDE – but at increased risk of accepting a chance difference as real.

Analyzing the Experimental Data

Experimental impact estimates are fundamentally comparisons of outcomes between two experimental groups (e.g., treatment and control) at some point after random assignment. Differences in raw means between the treatment and control group are unbiased estimates of the effect of the intervention. More precise (and still unbiased) estimates can be obtained by controlling for chance treatment-control differences in individual characteristics by regressing the outcome on a treatment indicator and a set of covariates X_j measured at baseline:

$$Y_i = a + b_j X_{ji} + cT_i + \varepsilon_i \qquad [1]$$

where Y_i is the outcome for the ith sample member, T_i is a dichotomous treatment indicator for the ith sample member (normally, treatment group = 1), ε_i is a random error term, and a, b_j, and c are coefficients to be estimated. The coefficient of T_i, c, is an estimate of the impact of the experimental intervention on the outcome Y (i.e., the treatment-control difference, controlling for X_{ji}).

The variance of the impact estimate is

$$V(c) = V(\varepsilon_i)\left[\frac{1}{n_\mathrm{t}} + \frac{1}{n_\mathrm{c}}\right] = V(Y_i)(1 - R^2)\left[\frac{1}{n_\mathrm{t}} + \frac{1}{n_\mathrm{c}}\right] \qquad [2]$$

where R^2 is the multiple correlation coefficient for eqn [1], n_t and n_c are the numbers of sample members in the treatment and control groups, respectively, and $V(Y_i)$ and $V(\varepsilon_i)$ are the variances of the outcome and the error term in eqn [1], respectively. As can be seen from this formula, explaining the variance of the outcome is equivalent to an increase in sample size. For example, an R^2 of 0.20 is equivalent to a 25% increase in sample size.

Any baseline characteristics can be used as a covariate. The best covariate is usually the baseline value of the outcome (if it exists), because it captures all of the unmeasured influences on the outcome that do not vary over time. *No* variable that measures behavior or circumstances after random assignment may be used as a covariate because such variables may be affected by random assignment. If so, they may capture some of the treatment–control difference caused by the intervention and result in a biased impact estimate. Thus, for example, it is illegitimate to include measures of the amount of treatment the participant received ('dosage').

A second set of restrictions on impact estimation is that outcomes for both treatment and control groups must be measured in the same way and at the same point in time *relative to the date of random assignment*. Differences between groups in either of these regards may create differences in measured outcomes that are not attributable to the intervention and therefore yield biased impact estimates.

Researchers typically use a t-test based on an estimate of the variance of c to determine whether the estimated impact is larger than could be expected by chance alone. (Note that the expression for the variance of the impact estimate in eqn [2] relies on the population value of the variance of the outcome. Researchers use the sample estimate of that variance to obtain an estimate of the variance of the impact estimate.) Typical significance levels used in social experiments are the 0.10 and 0.05 levels (two-tail test).

Researchers typically estimate impacts on multiple outcomes and conduct 'subgroup analyses' in which they define multiple mutually exclusive, exhaustive subgroups of the sample and estimate impacts on each. This approach creates a 'multiple comparisons' problem. The standard t-test used in such analyses is based on the assumption that the test is performed a single time. When multiple tests are performed, the chance that *at least one* of them will indicate statistical significance by chance alone is higher than the nominal significance level – and if many tests are performed, as they often are, the chance of such a Type I error may be very high. There is at present little agreement within the research community on how this issue should be addressed. An approach that seems to be gaining favor is to separate the estimates into one or

more 'confirmatory' tests of the main impacts that matter for policy and a set of 'exploratory' tests (usually including all subgroup analyses) that are intended to inform the interpretation of the confirmatory tests and/or suggest opportunities for further experimentation. Other suggestions for alleviating the multiple comparisons problem include limiting the confirmatory tests to a small number of central outcomes, using an index of outcomes for the confirmatory test, and/or adjusting the test to take account of the number of impacts estimated. (For the best existing statement of this issue, see Schochet (2008).)

Internal Validity and External Validity of Experimental Estimates

Evaluation methods that provide unbiased estimates of the impacts of a program, policy, or practice *on the population to which they were applied* are termed *internally valid*. Properly implemented social experiments provide internally valid impact estimates. To be most useful for policy purposes, however, impact estimates must have both internal validity and external validity. '*Externally valid*' estimators provide unbiased measures of the impacts of the intervention *on the policy-relevant population* – i.e., the population that would be affected by the policy decision that the evaluation is intended to inform. (The requirement that the estimated effect on the larger population be unbiased implies, in general, that to be externally valid an estimator must also be internally valid.) That is, only if the experiment faithfully implements the program, policy, or practice for a sample that is representative of the policy-relevant population will the findings have external validity and serve as a reliable guide for making decisions about broader adoption of the treatment studied.

The external validity of the study findings can be compromised in a number of ways. For example, for reasons of cost and logistics, experimental samples are usually clustered in a small number of locations – for example, a few schools, welfare offices, housing authorities, or health clinics. This makes it difficult to draw a sample that is truly representative of the policy-relevant population. In fact, experiments are frequently conducted in only one or two localities that cannot claim to be representative of the nation, state, or other jurisdiction for which policy is made. (See Olsen et al. (2013) for a derivation of the bias that may occur when experiments are conducted with nonrepresentative populations.)

In the end, true external validity is an ideal that is almost impossible to attain, if only because the continually evolving policy process represents a moving target. Nevertheless, it is an important ideal to strive for, and in assessing the strengths and weaknesses of alternative evaluation methods or results, it is important to gauge both the external and internal validity of the findings.

Is Experimentation Ethical?

Because they are the only known way to be confident of obtaining unbiased estimates of the impacts of interventions (that is, of avoiding the risk of selection bias), experimental-design studies have become the preferred method of program evaluation among most of the policy research community and among a growing number of policymakers (Baron, 2005; Cook, 2007; Cook and Foray, 2007; Boruch and Mosteller, 2002). But such designs are also subject to a widespread concern, especially among program practitioners: Do they violate ethical standards by denying program services to the control group?

It should be noted at the outset that posing the question this way *presumes* that the program services are beneficial. This is not necessarily the case. Perhaps the most common outcome of careful impact evaluations is a finding of no significant effect of the treatment; in a few instances, Peter Rossi famously expressed this as the Iron Law of Evaluation: "the expected value of any net impact assessment of any large scale social program is zero" (Rossi, 1987). Although this is probably an overly pessimistic assessment, it is true that many social interventions, when carefully evaluated, have not shown evidence of effectiveness. See Orr et al. (1996) and Burtless (1985) for examples of social policy interventions that were found to be outright harmful. In medicine, a number of relatively standard treatments have been found to be harmful when subjected to randomized clinical trials, as in the case of estrogen therapy for postmenopausal women (Women's Health Initiative Steering Committee, 2004). In fact, the very existence of the evaluation is evidence that the agency that funded it is uncertain about the value of the intervention. Thus, the fact that the control group is denied program services does not automatically mean that the control group is disadvantaged by the study.

Nevertheless, it is important to know whether controls are in fact denied services in any meaningful sense. A full discussion of the ethics of social experiments is beyond the scope of this article. (For a more detailed discussion of the ethics of social experiments, see Gramlich and Orr (1975) and Orr (1999).) Here, we simply note that if the supply of services is limited, as in a special demonstration or a budget-constrained program, random assignment can be viewed as simply one way to ration scarce resources. In such cases, in the aggregate, the same number of people will be served whether the fixed supply of services is allocated on a first-come-first-served basis, through staff judgment, or by random assignment of applicants from the larger eligible population. Indeed, random assignment is arguably fairer than other allocation methods because it gives every eligible applicant the same chance of receiving services. Only when all eligible individuals would receive services in the absence of the experiment would random assignment to a control group constitute denial of service in the aggregate. Random assignment to a no-service control group is generally viewed as inadmissible in the context of such 'entitlement' programs.

In considering whether experiments are ethical, it is important not to focus exclusively on the issue of denial of the focal treatment to controls. Other members of society have a stake in whether the experiment is performed. In particular, failure to obtain reliable estimates of the efficacy of an ongoing program, policy, or practice can impose substantial costs on taxpayers. Moreover, failure to identify programs that are ineffective implicitly imposes costs on their intended beneficiaries. Not only do ineffective strategies waste time and create false expectations, but they also consume resources that might otherwise be devoted to more effective ways to address the needs of the

target population. Thus, 'protecting' intended beneficiaries of new initiatives from experiments is not necessarily in their best interest.

A Brief History of Social Experimentation

Dehue (2005) credits the statistician and psychologist Sir Francis Galton with originating the concept of determining effects through statistical comparison of a treated group with an untreated group – essentially, the comparison group design (Galton, 1872). However, the principle of casting of lots to generate comparison groups in assessing the effects of treatments had been suggested over 200 years earlier by the Flemish physician Van Helmont (1662). And in 1835, Pierre Louis clearly proposed the use of comparison groups in medical research, suggested the use of random ('indiscriminate') assignment to treatment, and showed that he understood the relationship between sample size and the precision of the estimated difference in outcomes (Louis, 1835, pp. 75–76; Louis, 1836, pp. 59–60).

It was only after the turn of the twentieth century, however, that researchers began using comparison groups to test the efficacy of alternative social interventions. Led by the educational psychologists, researchers began using treatment and comparison groups (often entire classes of students) to test the effects of classroom circumstances such as fresh versus ventilated air, the gender of the teacher, memorizing methods, and educational measures such as punishing and praising (Dehue, 2005).

As researchers gained experience with the comparison group method, however, they became increasingly concerned – and their critics became increasingly aware – that the measured differences between treatment and comparison groups might reflect more than just the effect of the treatment; they might also include preexisting differences between the two groups. To protect against this form of bias, it became customary to obtain baseline measures of traits, such as intelligence, that might affect the outcomes and then to attempt to match the two groups on these traits. It soon became evident that such matching procedures were not only time-consuming and expensive, but were also far from foolproof; to be sure of an unbiased estimate of the treatment effects, the researcher had to correctly identify and measure *all* the characteristics on which the two groups might differ that could affect the outcomes of interest.

The power of random assignment to eliminate this source of bias by establishing comparable groups was recognized by William A. McCall in his 1923 book *How to Experiment in Education*. Again, the influence of psychology on education research was evident: McCall was a student of, and collaborator with, the renowned psychologist Edward L. Thorndike. The earliest study we have found in which a randomized design was actually applied to form a control group to assess the impact of an intervention was J.E. Walters (1931) study of using college seniors as counselors for 'delinquent' freshmen (Forsetlund et al., 2007, p. 377). (The authors describe the Walters study as the second to use random assignment. However, the earlier study that they identify (Remmers, 1928) actually ranked students by test scores and used alternate names on the list to form the treatment and control groups. Because this is not a random process, it does not meet our definition of random assignment. In fact, alternation had been used over 30 years earlier in a study of serum treatment for diphtheria, in which patients admitted to a hospital on alternate days formed the treatment and control groups (Fibiger, 1898; discussed in Hrobjartsson et al., 1998).)

Over the decade 1925–35, the great statistician R.A. Fisher laid the statistical foundations of experimentation with random assignment in his seminal books *Statistical Methods for Research Workers* (1925) and *The Design of Experiments* (1935). Mann (1949) provided the rigorous mathematical basis for many of the methods described in Fisher's seminal books.

In the 1930s and 1940s, random assignment gained increasing favor among educational psychologists as the ideal method for comparing different teaching methods, although the number of randomized experiments was still small. (In an 'extensive search,' Dehue (2005) found one randomized experiment in the 1930s and six in the 1940s. Forsetlund et al. (2007) found three randomized trials in the 1930s and six in the 1940s prior to the well-known randomized controlled trial of streptomycin for pulmonary tuberculosis, which is widely regarded as the first clinical trial in medicine (British Medical Research Council, 1948).) By the 1950s, statistical procedures for the design and analysis of relatively complex experiments were firmly established by researchers and statisticians (see, for example, Mann, 1949; Cochran and Cox, 1950; Lindquist, 1953). Campbell and Stanley's (1963) classic, *Experimental and Quasi-Experimental Designs for Research on Teaching*, clearly laid out all of the issues we have discussed so far (published in 1966 as *Experimental and Quasi-Experimental Designs for Research*).

Application of Experimental Methods to Social Programs, 1960–2000

By the 1960s, the use of the experimental model was sufficiently widespread in education, psychology, and medicine that it was quite natural to apply it to social programs and policies outside those fields. In 1961–64, for example, the Manhattan Bail Bond project used random assignment to test the proposition that many arrestees could successfully be released without bail prior to trial (Botein, 1965). Other randomized tests of law-related programs and procedures undertaken in the 1960s included studies of a variety of approaches to the prevention and treatment of juvenile delinquency; the use of legal counsel in juvenile court; the effects of pretrial conferences; low-stress versus high-stress training for police; alternative penalties for drunk driving; and vocational, surgical, and social rehabilitation for former prisoners (Riecken and Boruch, 1974).

These early applications to social policy received little attention outside the immediate circles of the researchers and funding agencies involved. In the late 1960s and early 1970s, however, a series of four experiments in income maintenance (that is, cash transfers to low-income families) attracted much greater attention, both within the research community and among policy makers. (For an overview and critique of the income maintenance experiments, see Rossi and Lyall (1978).) Launched by the U.S. Office of Economic Opportunity and the Department of Health, Education, and Welfare (HEW),

these studies were novel in several respects. First, their samples were much larger than most of the randomized trials that had gone before, ranging from about 1300 families to nearly 5000 families. More importantly, these were *field* experiments: they involved administering carefully controlled treatments to, and observing the behavior of, these large samples of individuals in the course of their daily lives, not in classrooms, hospitals, psychology laboratories, or other institutional settings. In addition, the question addressed by the experiments – whether receipt of cash transfers (welfare) would cause poor families to stop working – was a highly visible, politically charged issue. These were perhaps the first experimental tests of an issue that national policymakers really cared about.

These highly visible studies of a politically controversial issue prompted other federal agencies to adopt this novel technique in the early 1970s. Large-scale experimental tests of housing vouchers by the Department of Housing and Urban Development, and alternative health insurance plans by the Department of Health, Education, and Welfare (HEW), were explicitly patterned on the income maintenance experiments (Kennedy, 1980; Newhouse, 1993).

In the mid-to-late 1970s and early 1980s, experiments were conducted by the U.S. Department of Labor and other funding agencies to test alternative employment and training services for unemployed workers, welfare recipients, disadvantaged youths, ex-offenders, former substance abusers, and individuals with mild to moderate retardation. In 1981, when federal legislation gave states the option of testing new approaches to the employment of welfare recipients under federally approved waivers of their statewide plans, the Department of Health and Human Services (HHS, formerly HEW) took the opportunity to require that such projects be evaluated using random assignment of eligible program applicants to treatment or control (services-as-usual) condition. This led to 15 years of waiver experiments, leading to the passage of major welfare reform laws in 1986 and 1996. (See HR 3734, 'Personal Responsibility and Work Opportunity Reconciliation Act of 1996,' 9 August 1996. The findings of many of these experiments are summarized in Greenberg et al. (2009).) According to Greenberg and Shroder (1991, 1997, 2004), by 1980, 55 social experiments had been initiated in fields other than medicine and education; by 1995, 195 such experiments had been conducted; and by 2004, at least 273 had been initiated. (Greenberg and Shroder define social experiments as "field studies of social programs in the United States in which there was random assignment of individuals or families to alternative treatments and an emphasis on the measurement of impacts on either market behavior, the receipt of earnings, or transfer payments." Thus, they explicitly do not include in their compendium experiments involving interventions such as drug treatment, medical care, or education programs.)

Application of Experimental Methods to Social Programs, 2001–14

The broad acceptance of social experimentation as the 'gold standard' of program evaluation in the 1980s and 1990s took the form of a number of individual experiments being approved and conducted largely in isolation of one another. In the 2000s, experimentation began to become more institutionalized.

With the institution of the Program Assessment Rating Tool (PART) in 2002, the powerful Office of Management and Budget (OMB) began not only to require that federal agencies systematically evaluate the effectiveness of their programs, but to do so with random assignment wherever feasible. Although PART was discontinued at the end of the Bush administration, OMB under President Obama has continued to press agencies to provide hard evidence of program effectiveness, in the form of randomized trials wherever possible. (See, for example, Zients (2012), a memorandum from the Director of OMB to agency heads, requiring agencies to include in their budget submissions discussion of innovative evaluation approaches and offering technical support and resources to assist them in implementing rigorous evaluations, including random assignment.)

A second important impetus to experimentation came with the establishment of the Institute of Education Sciences (IES), also in 2002. IES's first director, Grover (Russ) Whitehurst, aggressively pursued randomized trials of educational interventions, both existing and proposed. In a field that had seen few social experiments in the previous 40 years, IES launched more than 30 in its first 10 years, through its National Center for Education Evaluation and its network of 10 Regional Education Labs. In fact, virtually all of the major studies initiated by IES during that period were randomized trials. (As noted above, education researchers pioneered the use of random assignment in the 1920s and 1930s. However, in the latter part of the twentieth century, the field largely abandoned the method until it was revived at IES.)

Under the Obama administration, the link between social experimentation and policy has been strengthened by a set of 'evidence-based policy initiatives' – appropriations reserved for funding programs that have been proven effective in well-designed randomized trials. Administered by the Corporation for National and Community Service and the Departments of Health and Human Services, Education, and Labor, these appropriations totaled $1.3 billion in fiscal year 2011 (Haskins and Baron, 2011). The funds are allocated to support evidence-based programs in education, teen pregnancy prevention, home visiting, innovations in community service, and workforce interventions.

Abstract

This article discusses the growth of and change in social geography since the 1960s. Early preoccupation with positivism and statistical description gave way, first to a behavioral approach and subsequently to a variety of 'radical' approaches. These attempted to challenge the inequalities and injustices of contemporary society. The article examines the subsequent impact of feminist and postmodern ideas and the associated growth of cultural geography on social geography. Over the last 20 years, social geography has had an uneasy relationship with cultural geography and has lost status in the USA. Recent publications concerned with social geography have argued for the importance of some of its traditional concerns and for radical changes in its approach.

Introduction – When and What

Social geography emerged as a significant subdiscipline during the 1960s as part of exciting theoretical and methodological change that geography experienced during that decade. In the 1970s and 1980s, vigorous theoretical debates led to a variety of conflicting approaches to research in social geography. By the early 1980s, the subdiscipline was of major importance within human geography. Indeed, it was claimed that it became "virtually synonymous with the whole field of human geography" (Johnston et al., 1994: p. 562). But the growing prominence of cultural geography since the end of the 1980s has reduced the prominence of social geography.

The rapid growth of the subdiscipline and the significant theoretical debates within it involved shifts in its definition and practice. In 1965, Pahl suggested that it was about "the theoretical location of social groups and social characteristics, often within an urban setting" (p. 82). In 1975, Emrys Jones argued that "social geography involves the understanding of the patterns, which arise from the use social groups make of space as they see it, and of the processes involved in making and changing such patterns" (p. 7). The emphasis on social groups evident in Pahl's earlier definition remains of particular importance, in that what is held to make social geography 'social' is its concern not with individuals but with people as members of groups. However, there are some significant changes between the two definitions. First, Jones' definition introduces the idea that social processes produce spatial patterns and vice versa. This understanding of social geography remained dominant into the 1980s. Second, Jones' phrase "the use social groups make of space *as they see it*" (author's emphasis) signals an increasing interest in people's subjective experiences of space and place – an interest that has become increasingly prominent.

The understanding of the scope and aims of social geography implied in Jones' definition endured until the mid-1980s when it came under increasing attack. These attacks and their implications for the development of social geography make better sense in the context of an account of the type of research that social geographers did from the 1960s to the mid-1980s, presented below.

Engaging with Positivism

Describing the Social Characteristics of Urban Areas

A major focus of research during the late 1950s and 1960s was the statistical description and analysis of the characteristics of the populations of urban areas. Central to this project was the identification of systematic patterns in the location of different social groups. Analysts examined which groups were likely to be segregated from other groups and whether there was evidence for particular patterns of location for different groups within cities.

At this time, there were also moves within human geography to apply positivist philosophy and methodology to the pursuit of geographical knowledge. These moves encouraged, on the one hand, attention to clearly specified theoretical statements and predictions and, on the other, the use of quantitative data and statistical techniques that were considered to ensure rigorous, scientific testing of hypotheses. Also associated with the growing commitment to positivism was a desire for predictive models of the location of human activity and people's 'spatial behavior,' often drawing on neoclassical economics. Geographers interested in social groups and in cities sought to develop predictive theories of the spatial form of cities, including theories of the location of social groups within urban areas.

Geographers looking for theoretical and methodological inspiration turned to the work of urban sociologists. First, they drew upon the work of the Chicago School – including Louis Wirth, Robert Park, and Ernest Burgess – who carried out extensive studies of Chicago in the first half of the twentieth century. They had used maps of a wide range of statistical information in order to identify the 'natural areas' – residential areas with distinctive physical and cultural characteristics – that the Chicago School sociologists argued developed from unplanned processes of competition and cooperation among urban residents. Burgess had developed a general model of urban residential land use as a series of concentric zones focused around the Central Business District.

Second, urban geographers were drawn to the work of Eshref Shevky and Wendell Bell who studied characteristics of the populations of Los Angeles and San Francisco. Shevky and Bell (1955) argued that the 'increasing scale' of society resulting

from the increasing complexity of economic organization and the associated growth of urban areas could be linked to three dimensions of urban residential differentiation: 'social rank' or 'economic status'; 'urbanization' or 'family status'; and 'segregation' or 'ethnic status.' A key feature of their work was the development of 'social area analysis' using data on census tracts. They selected variables to represent the three dimensions and then used these to categorize census tracts in terms of 'high' or 'low' economic, family, or ethnic status. Although the theoretical links between increasing societal scale and the three dimensions: economic, family, and ethnic status were poorly specified and strongly criticized, geographers enthusiastically embraced the use of census data to characterize areas of the city.

The advent of powerful computers in the 1960s allowed geographers to use sophisticated statistical techniques to analyze data on census tracts. Factorial ecology was particularly popular – the use of factor analysis or principal component analysis to identify a few general constructs that underlie a large number of variables. Shevky and Bell's three status dimensions often emerged from the census data. The analyst could also classify census tracts in terms of the underlying constructs and map the results to see whether any systematic spatial patterns in characteristics of census tracts could be identified. These maps were compared with Burgess' concentric model of urban form and comparisons between factorial ecologies of different cities also made. Similar techniques were also used to look for relationships between residential differentiation, location, and patterns of crime, deviance, and mental health.

The availability of census data for many cities (mostly in the 'developed' world) and increasing access to computers allowed social geographers to indulge in an orgy of analysis. However, there were some clear limitations to this work. First, the nature of the constructs identified was limited by the available census data: they could be as much a reflection of the data available as of the social 'reality' of urban areas. Second, because the data related to areas rather than individuals, false associations between variables may have been made (the 'ecological fallacy'). Moreover, differences in the sizes and rules for creating census tracts between countries limited the comparability of the results. Third, although the practitioners of these analyses aspired to work within a positivist framework much of the research was inductive description rather than tests of clearly specified hypotheses linked to well-identified theoretical propositions. Nevertheless, this body of work provided a considerable amount of descriptive information on residential differentiation that has become part of the taken-for-granted knowledge of geography.

The Behavioral Challenge

The descriptive analysis of urban residential characteristics was not the only type of work in social geography done during the 1960s and early 1970s. There were those who, despite their hopes for a positivist approach to the development of theory within geography, were dissatisfied with the widely used approaches to studying human behavior.

In the 1960s, much research in human geography drew its inspiration from models, which posited that people possessed perfect information and were rational and optimizing in their behavior. Dissatisfaction with these assumptions prompted some researchers to turn to psychological theory concerned with cognition and decision making in order to investigate what information people had available to use in spatial decision making and how they used it. The principal method employed in these studies was the questionnaire survey, frequently incorporating some variety of attitudinal and personality test drawn from social psychology. The research carried out within this broad framework is known as 'behavioral geography.'

Work in behavioral geography was concerned with the locational decision making of firms, individuals' decisions over where to live, people's everyday movements, and their information and ideas about space and place. Gould's work on mental maps was particularly influential (Gould and White, 1974). The idea of an incomplete, biased, and personal vision of the spatial world conjured up by the term 'mental map' became part of geographers' ideas about how people made decisions about both everyday movement and migration. Research on how people searched for information in space and developed strategies for choosing locations was also recognized as important in studies of residential mobility and of people's everyday travel behavior. In the former, researchers were influenced by the early work of sociologist Peter Rossi whose 1955 book *Why Families Move* was subtitled *A Study in the Social Psychology of Residential Mobility*. A large number of studies of residential mobility in different cities and countries resulted. In the latter, diary data on travel behavior were used to develop inductive theories about the way people choose and order travel destinations.

Research using the perspectives of behavioral geography – while part of social geography – remains marginal to the field because of its focus on the individual rather than on people as interacting with and partly constituted by their social milieu. However, the importance of people's social milieu is evident in much of the work actually carried out. Researchers often examined contrasts between individuals drawn from different social groups (for example, different income, class, age and, occasionally, gender groups). Others examined the influence of the resources available to individuals on their spatial cognition and so ended up investigating differences between social groups. The research is also significant to social geography because criticisms of its individualistic approach were important to the development of alternatives.

'Radical,' Politicized Approaches

During the early 1970s, many geographers became dissatisfied not only with the philosophical approach of positivism, but also with the lack of critical political engagement that they detected in contemporary research. These concerns grew out of the radical ideas promoted in America and Europe as part of opposition to the American war in Vietnam, antinuclear campaigns (especially in Britain and European countries), civil rights campaigns (particularly in America), and the growing 'rediscovery' of poverty in the prosperous countries of the West. What was needed, it was felt, was research that could suggest how to change society, not merely how to understand it. Positivism was criticized for suggesting that an objective approach to social science was necessary, feasible, and desirable

and that it was possible to find 'universal laws' of human society. Competing 'radical' approaches were proposed; they all shared the desire to challenge the inequalities and injustices of contemporary society although some sought this through changing our valuation of human beings, some through institutional change and some through revolutionary political action. A sketch of some of the main approaches follows. Although here they are separated into demarcated 'boxes,' in reality their boundaries were fuzzy.

Humanistic Geography

The humanistic geography that emerged in the 1970s was animated by a desire to present an alternative to positivism. It shared the behavioral geographers' critique of some positivist approaches as dehumanized – insofar as they did not engage with individuals' subjective experience. However, they added to this the more fundamental criticism that positivist social scientists made false claims to objectivity – by failing to recognize the subjectivity of both the observed and the observer. Here, humanistic geography made a decisive break with positivism and turned to approaches, which require empathy with people's own perception of the values and meanings that inform their action (Jackson and Smith, 1984). Two other important features of humanistic approaches were the insistence that people were active agents shaping their own worlds and a fascination with the links between place and social identity.

Although links have been made between the humanistic geography of the 1970s and a variety of early work in geography, the most immediate influence was the Chicago School. One of the major strands of work focused on understanding the way of life of particular social groups in particular areas of a city (although a few studies of rural areas were also carried out). It used ethnographic methods including participant observation, firsthand observation, and interviews as well as documentary information and census materials. Other researchers used ethnographic methods to explore features of crime and deviance in selected neighborhoods, often using factorial ecology to identify suitable areas for study.

Humanistic geographers also engaged with what were for 1970s geographers the new philosophical approaches of phenomenology and existentialism, with two important consequences. The first was a move toward thinking of the individual as constituted through the social interactions in which he/she takes part. These social interactions and people's everyday behaviors create a taken-for-granted world, which the social scientist can attempt to deconstruct. Second, there was an attempt to avoid prior theorization about the values and meanings of those people who are studied and to be open to understanding the world through their eyes. However, this still allows the findings of such studies to be interpreted within a theoretical or practical context and for disagreement about such interpretations to be fierce.

Another focus was on understanding the cultural meanings of, and values attached to, particular landscapes and built forms. This work employed the methods of hermeneutics (for example, Meinig, 1979). In the 1970s, this work was considered to be on the margins of social geography and soon became seen as part of the revival of cultural geography. Its investigation of the multiplicity and instability of meanings, their communication and reformulation began a tradition of work that has had important implications for contemporary social geography.

Welfare and Weber

David Smith's *Human Geography: A Welfare Approach* (1977) addressed what had begun to emerge as a new approach to human geography of particular significance to social geography. This approach focused on 'who gets what, where, and how' – that is, on issues of social justice and inequality. It therefore involved both arguments about what constitutes social (and often, territorial) justice and attempts to measure empirically various types of social inequality. An early focus was on developing social indicators to measure inequality between social groups living in different areas at a variety of scales ranging from the city to the world. This research was built on the expertise developed in earlier descriptive analyses of census data on cities. It also included measurement of people's spatial access to services (for example health care or education) or proximity to negative factors such as pollution. In order to explain the patterns of inequality or deprivation they identified, researchers developed analyses of the operation of agencies and agents whose actions seemed significant to the distribution of resources.

A substantial body of work was developed around state and private institutions' management of the distribution of resources drawing on the theories of Max Weber. The concept of 'managerialism' was first proposed by Pahl (1975), who suggested that within both the state and private sector there were 'gatekeepers' whose decisions were crucial to people's access to resources. Within social geography, this idea stimulated a wide range of studies of access to housing, emphasizing the constraints on people's choices in the housing market. The theme of choice and constraint was explored in access to health care, education, services for the elderly, parks, and open space and delivery services in rural areas. The ideas of Weber also introduced an increasing interest in conflict between and among institutions and groups. Here social geographers drew upon the ideas of the sociologist John Rex (1968) on housing classes, as well as on Weberian ideas about the operation of bureaucracies and professional groups, to explore conflicts over the distribution of resources.

A different approach to access used the ideas of time geography developed by Hagerstrand (1975). He suggested that time and space are resources people must use to realize the 'projects' they wish to carry out. Since traversing space requires time and many activities require the copresence of individuals or presence at a particular location, not all projects can be realized. People's ability to carry out particular projects is limited by capacity, coupling, and authority constraints. Despite the enthusiasm of some geographers and a few empirical studies, the potential of these ideas remained regrettably underdeveloped. Most empirical use of Hagerstrand's ideas focused on physical limits to access and did not develop the possibilities of a more fully realized social theory of human behavior in space and time.

Although the majority of welfare-focused research was concerned with cities in 'developed' countries, attention was

also paid to inequalities in the rural areas of such countries and to developing countries, Eastern Europe and the former USSR. The study of conflict and constraint often employed ethnographic methods to explore the values and patterns of behavior of gatekeepers and the social groups attempting to access resources. Attempts to answer the 'how' element of welfare geographers' problematic often drew on theories of political economy, which situated explanation of issues such as housing access within an analysis of the operation of capitalist society.

Marxist Approaches

The book that best illustrates the thinking that drew geographers to Marxist theory is Harvey's *Social Justice and the City* (1973), which explains the shift in Harvey's thinking from liberal to Marxist. By the end of the 1970s, Marxist approaches had expanded to create a new orthodoxy. With implications across all geography, Marxist approaches were embraced with particular enthusiasm in social geography.

The analysis of residential differentiation and change had been a central part of social geography since its inception. Marxist theory offered ways of understanding these processes through ideas of class struggle and capital accumulation. Large-scale patterns of investment and disinvestment in the built environment could be interpreted in terms of crises in processes of accumulation. Such analyses were applied to gentrification and suburbanization. Processes of socialization within residential areas could also be theorized as involving the reproduction of particular social subgroups (class fractions).

These early formulations were challenged by a body of socialist–feminist work that developed in the early 1980s. While incorporating many postulates of Marxism, this work criticized the conceptual and practical neglect of gendered power relations and the failure to identify and explore the links between gender and class relations. Critical empirical research on both gentrification and suburbanization sought to explore the ways in which gender relations were involved in the construction of the spatial structure of the city and the implications of these processes for women's oppression in society. In general, this socialist–feminist work was more sensitive than other Marxist approaches to the role of human agency and to humanist claims concerning the partiality of knowledge.

Analysis of access to services was also strongly affected by Marxist theory. Castells' work on collective consumption and social movements was highly influential. Castells (1976) defines collective consumption as the provision of services that are produced and managed collectively and distributed through nonmarket allocation processes. He argued that these were provided through the State because, while necessary to the reproduction of labor power, their provision is not profitable enough to warrant involvement of the capitalist market. Castells made a highly contentious definition of the city as "a unit of collective consumption corresponding more or less to the daily organization of a section of labor power" (1976: p. 148). More important to research in social geography, he spelled out how social movements might arise in response to inadequacies in the provision of collective consumption. Such social movements might fragment class solidarity and reduce the possibility of radical political change or enhance it. Castells' ideas stimulated extensive conceptual and empirical research in both urban sociology and in social geography.

Critiques and Cross Fertilization

By the early 1980s, social geographers had become better versed in social theory and more critical and sophisticated in its application. There were debates and cross fertilization of ideas among researchers working in the three areas identified above and increasing awareness of their shortcomings as well as their strengths. Humanists and feminists raised critiques of Marxist approaches' neglect of human agency, which encouraged geographers' interest in the sociologist Anthony Giddens' 'structuration' theory (Giddens, 1981). Giddens attempted to show how human agency and structures were mutually constitutive within a time-space framework that drew on Hagerstrand's ideas. These critiques encouraged attempts to develop a more 'humanistic' Marxism sensitive to both human agency and contingency. At the same time, those concerned with issues of welfare and social justice were increasingly using some form of political economy approach deriving from Marxism to frame their research. Feminist geographers criticized these approaches for neglecting gender, and a major new body of research by feminist social geographers began to develop. This work involved ethnographic empirical study of the everyday life of women and incorporated and reshaped ideas drawn from welfare geography (in relation to issues of access and inequality), humanistic geography (in relation to women's experience of and social relations within particular places), and Marxist geography (in relation to class and economic power). Some of these feminist works were linked to another major development within geography – the explosive growth of cultural geography during the late 1980s.

This new cultural geography drew on earlier humanistic social geographical research as well as on cultural studies and feminist and postmodern critiques of modernist theory. In particular, modernist theory was criticized for assuming a white, bourgeois, and masculine subject and for its attempts to discover universal truths. Furthermore, postmodern theory insisted that because meaning is constantly created and changed through shared but contested discourses, both individual and group definitions are unstable and contested. These critiques, and empirical studies in the 1980s and 1990s in cultural and economic geography, call into question earlier definitions of social geography and the coherence of the subdiscipline.

Fragmentation and New Theoretical Directions

The later 1980s and the 1990s saw a progressive destruction of the main features of Emrys Jones's (1975) definition of social geography. That definition involved separating social process and spatial pattern and focusing on the use of space and creation of spatial patterns by social groups.

Social Process and Spatial Pattern vs 'Spatiality'

The 1980s saw growing dissatisfaction with the idea of social processes as distinct from spatial patterns, on the grounds that,

because all social interactions necessarily take place in and through space, spatial pattern cannot be isolated from social process. These attacks derived from critiques of positivist analyses of abstract space as an empty container of social processes. Instead, Marxists argued that space was produced through capitalist social processes and through processes of class and other groups' opposition to capitalism. Humanistic and cultural geographers used phenomenological theory and empirical research to argue that understandings of space are produced through people's everyday social activities and do not draw on prior concepts of abstract space. The term 'spatiality' was coined to refer to the inescapable imbrication of space and social practices.

Defining 'The Social'

Feminist work in the 1980s showed that social geography's focus on issues of social reproduction – housing, education, health care, and crime – had been seriously incomplete. Domestic labor and the home had been ignored, as had the significance of gender relations. Moreover, this feminist work also argued that "production and reproduction – the conventionally accepted subjects of economic and social geography respectively – cannot analytically be separated" (Bowlby and McDowell, 1987: p. 305). During the 1990s, the importance of examining the social relations embedded in economic exchange was re-emphasized by a number of researchers. In particular, feminist research on labor markets showed clearly the interpenetration of the social and the economic (Hanson and Pratt, 1995).

The early work of social geographers focused on the implications of people's membership of social groups. The existence of defined social groups and the salience of characteristics such as ethnicity, income, and, much later, gender, were largely taken for granted. The theoretical critiques developed in cultural geography during the later 1980s and early 1990s drew attention to the fluidity, socially constructed, and contested nature of definitions of social groups and the significance of struggles over representations of identity. In the 1970s and early 1980s, despite fierce arguments over explanations for social inequality, the relevance of political economy theories was generally accepted. Postmodern approaches questioned the validity of 'grand theory' such as that of Marx and Weber that had previously been part of the stock in trade of social geographers. Cultural geographers' engagement with the theories of Foucault changed the ways in which 'power' was conceived. Developments in cultural geography have thus required social geographers to examine processes of representation and communication more closely, to revise their theories of the operation of social power, and to question the idea of a single 'social reality' to be uncovered through research.

Furthermore, the rise of interest in nonrepresentational theories in cultural geography from the mid-1990s posed a new challenge to social geographers' understanding of the 'social.' Nonrepresentational theories argued that researchers should go beyond a focus on representation and meaning to consider the complicated ways in which human interactions with each other, with the material world, and with nonhumans create new, emergent capacities to act. Bodily practices are understood to involve precognitive affects created in interactions that are not dependent upon the understanding of the rational subject. Such approaches called into question social geographers' focus on analyzing people's accounts of their experiences and practices as members of social groups and prioritized study of affects and everyday, mundane "doings" (Dewsbury et al. 2002: p. 438).

Making a Difference?

The exciting theoretical concerns posed by cultural geography led to a shift in empirical focus in social geography toward embodied practices and the microprocesses of social interactions and representation through which particular social identities and behaviors are created, valued, and devalued in different places. For many social geographers the growth of cultural geography presented an opportunity to combine many of the themes of the two subdisciplines in fruitful investigation of social inequality and difference and to focus on and destabilize definitions of a wider range of 'social groups' – such as disabled people and gay and lesbian people. In 1988 the '*Social Geography Study Group of the IBG*' (which had been formed in the early 1970s) changed its name to the '*Social and Cultural Geography Study Group*' and 11 years later the journal *Social and Cultural Geography* was founded. These developments exemplified a widespread enthusiasm for the idea that social geographers' tradition of political engagement and ethnographic research could combine positively with cultural geographers' sensitivity to discourse and symbolic expression of difference. Later this combination led to studies of embodied actions and to social and cultural geographers' interest in emotional geographies and geographies of embodiment.

Since 1990, the alliance of social and cultural geography has prompted concerns about the desocializing and depoliticization of social geography and a loss of focus on 'inequality' and 'relevance' – a focus that was central to social geography in the 1970s and 1980s. In the USA and to a somewhat lesser degree in the UK, much research that speaks to those concerns is presented as part of other subdisciplines such as urban geography, population geography, health geography, or geographies of social justice (Del Casino, 2011).

What Future for Social Geography?

Social geography is no longer the 'fashionable and radical' project that it was in the 1970s and early 1980s. Firmly part of the Anglo-American geographic tradition, social geography has largely ignored the intellectual challenges posed by the empirical realities of the developing world and the research of non-Western scholars. In a trenchant critique Peake (2011: p. 768) argues for "interrogation of the institutional whiteness of the discipline and of the white identities of its practitioners" and "openness to the incorporation of non-white knowledges into imaginaries of social geography."

The current period of austerity in the West and growing global and local inequalities pose important political and intellectual questions for geographers concerned with inequality. This challenge may lead to a revival in the importance of the disciplinary identity of social geography or to 'social geography' being carried out under the aegis of other subdisciplines. If social geography can rise to the challenges

Peake poses, it can become part of a movement to reorient human geography as a whole toward a full engagement with both the partiality and the importance of the variety of human geographical concerns and knowledges.

Abstract

The term 'social history' refers to a subdiscipline of the historical sciences on the one hand and to a general approach to history that focuses on society at large on the other hand. In both manifestations, social history developed from marginal and tentative origins at the end of the nineteenth and the beginning of the twentieth centuries, and experienced a triumphant expansion from the 1950s to the 1980s. Social historians sought to uncover the relationships between economic, demographic, and social processes and structures, as well as their impact on social stratification, political institutions, social movements, ideologies, and forms of 'public' and 'private' behavior. For the comprehensive variant of 'social history,' the term 'history of society' has gained currency. Class, social status, standard of living, the family, work, social mobility, inequality, modernization, conflict, race, and gender are central keywords in this historiography. Interdisciplinary contact with sociology, especially historical sociology, economics, demography, political science, and, more recently, anthropology and cultural studies has been intensive. The borrowing of concepts and even the adaptation of 'middle range theories' (R.K. Merton) as tools in historical research and writing is a trademark of social historians as compared to traditional narrative historians. Comparative studies have embodied the interest in the application and testing of theories and have brought social history closest to historical sociology.

The term 'social history' refers to a subdiscipline of the historical sciences on the one hand and to a general approach to history that focuses on society at large on the other hand. In both manifestations, social history developed from marginal and tentative origins at the end of the nineteenth and the beginning of the twentieth centuries and experienced a triumphant expansion from the 1950s to the 1980s. Throughout, social history can be best defined in terms of what it wants not to be, or against that to which it proposes an alternative.

On the one hand, social history distinguished itself from political history, which had been dominant during most of the nineteenth and the early twentieth centuries. Consequently, the 'social' in social history meant dealing with the structures of societies and social change; social movements, groups and classes; conditions of work and ways of life; families; households; local communities; urbanization; mobility; ethnic groups etc. On the other hand, social history challenged dominant historical narratives which were constructed around the history of politics and the state or around the history of ideas, by stressing, instead, social change as a core dimension around which historical synthesis and diagnosis of the contemporary world should be organized. With these aims in mind, social historians (including historical sociologists and economic historians) sought to uncover the relationships between economic, demographic, and social processes and structures, as well as their impact on political institutions, the distribution of resources, social movements, shared worldviews, and forms of public and private behavior. For the comprehensive variant of 'social history,' the term 'history of society' (*Gesellschaftsgeschichte*) has gained currency. Not only in Western Europe and North America but also in other parts of the world, the establishment, expansion, and specialization of social history belong among the significant trends of interwar and particularly postwar intellectual and academic life. Nevertheless, in recent years, it shares with other fields of the humanities and social sciences a 'time of doubts' (Chartier, 1993), a period of challenges from interpretative, constructivist, and discursive approaches (Palmer, 1990; Bonnell and Hunt, 1999).

Early Institutionalization (Late Nineteenth–Early Twentieth Century)

Like other generations of historians in the twentieth century that have at some point used the label 'new' for themselves, the claim to innovation by social historians in the 1960s and 1970s obscured the rich diversity of predecessors and competitors, which goes back to the second half of the nineteenth century (Kocka, 1986). In that period, the academic professionalization and disciplinary differentiation of economics, sociology, and political science on the one hand and history on the other, prevailed.

The mutual contact zones or, by contrast, the strength of boundaries, were marked by significant national differences. The resulting interactions and hierarchies between these "fields of knowledge" (Ringer, 1992) differed in respect of the amount of space they provided for historical approaches. The 'Historical School' of political economy in Germany, dominant in the last third of the nineteenth century, is a case in point. It was part of economics and did not gain much recognition in the discipline of history. Some professional historians took part in a process of specialization in 'social and economic history' that kept a critical distance as much from this strand of economics as from the traditional history of great men, events, and ideas. The development of the combined field 'social and economic history' marked a double opposition, on the one hand to the history of political events and on the other hand to an increasingly 'a-historical' economic science.

The creation of a specialized journal in Germany allows one to give a precise date to the development of this subdiscipline of historiography. In 1893 The Journal for Social and Economic

History, (which was continued after 10 years (and still exists today) as the *Vierteljahrschrift für Sozial-und Wirtschaftsgeschichte*) was founded under the direction of the Austrian socialist Ludo Moritz Hartmann and the conservative medievalist Georg von Below. That journal served as a direct reference for Lucien Febvre and Marc Bloch (*see* Bloch, Marc Léopold Benjamin (1886–1944)) when they founded the *Annales* in 1929 in Strasbourg. Not surprisingly, their journal was first called *Annales d'histoire économique et sociale* (1929–39). The international exchanges and mutual observation between some of the protagonists of historiographic innovations in the early decades of the twentieth century were intense. Thus, only 2 years after the French flagship, the Polish journal *Roczniki dziejow spolecznych i gospodarczych* (Yearbooks for social and economic history) appeared. These early journals shared a further characteristic which distinguished them from the mainstream political history around them, namely a keen interest for 'universal,' nonnationalistic history.

In Germany, social and economic history remained a specialized branch without much impact on general history. In England, economic history maintained close links to social themes. After World War II, the French *Annales* historians tended to move their journal away from its earlier identification with this 'subdiscipline.' Similarly, the program represented by Ernest Labrousse for a history of class relations taking as its starting point the economic 'basis,' broadened out more and more into the areas of urban history, quantitative analysis of social strata, and the integral description of regional societies. Where 'social and economic history' continued to be an institutionalized specialty, it did not necessarily figure as an area of major innovations, as was later the case with the 'new' history of the 1960s and 1970s.

These early efforts to establish a specialized field and an alternative view of history with 'society' as the main object, and organizing principle, of analysis were paralleled by similar movements in various countries. In the United States, the *New History* of the turn of the century; in France, Henri Berr with his *Revue de Synthèse (Historique)* starting in 1900 and the reception of Durkheimian sociology by historians; in Germany, the development of a historical sociology by Max Weber and others; and in Great Britain, in the first half of the twentieth century, the impulses of George Unwin and R.H. Tawney for the development of an economic history that included social and cultural factors, were all among the most influential strands of socio-historical thinking (Iggers, 1975).

Two characteristics of these debates and innovations deserve emphasis: the challenge of Marxism in a broad, nonorthodox sense provoked both emulation and animosity. Secondly, it is interesting to note in light of current discussions that, especially in the German context, the concept of 'culture' rather than that of 'society' was conceived as the vantage point for the synthetic organization of knowledge in the social sciences. In the 1950s the representatives of French 'new history' used the term 'history of civilization' to define the broadest possible framework of historical synthesis. Even Trevelyan's (1942) definition of social history as "the history of a people with the politics left out," which is cited as often as it is refuted, provides surprisingly wide room for the 'social,' to implicitly include culture, mentalities, and everyday life. (For a detailed treatment of the above topics *see* Historiography and Historical Thought: Indigenous Cultures in the Americas; History and the Social Sciences).

In recent times a further root of social history has attracted wider attention. It lies in the antimodern nationalist currents that are critical of industrialization which, in particular in the 1920 and 1930s, presented a special attraction for the younger social and human scientists. The interest in rural life, population, and race combined, particularly in Germany, with aggressive nationalism and criticism of the new political borders (Raphael, 1997). This historical writing opposed conventional research subjects and forms; it turned away from the state and classical political history, looked for alternatives to the traditional focus on elites, and took as its example the methods which had already seen much progress in demography, geography, and anthropology. In the 1930s and 1940s, a number of representatives of this so-called *Volksgeschichte* (history of the people) moved closer to National Socialism and became active as wartime political consultants. As some of these historians and social scientists played a significant role in the modernizing of the human sciences in the German Federal Republic, a debate arose as to the extent to which lines of continuity led from the 'history of the people' to social history, and concerning the relation between its representatives' rightist views and their proposed 'structural history' of modern industrial society (Schulze and Oexle, 1999; Conrad, 1999).

Postwar Expansion (1950s–70s)

Not only in Western Europe and North America but also in other parts of the world, the establishment, expansion, and specialization of social history belong among the significant trends of interwar and particularly postwar intellectual and academic life. The spread of the 'new' histories since the 1960s, occurred at a time when systems of higher education in Europe and North America were dramatically expanding. The general increase in academic jobs, student enrolment, and PhD candidates, as well as the massive growth in the publication of books and journals, allowed the various strands of social history to find ample space without replacing or pushing aside more traditional ways of writing and teaching history.

The institutional growth of social history followed different national directions. But it can generally be said that in the 1970s, a high point was reached in its establishment within universities and among the larger public. The most impressive indicator is the founding of new journals concentrated around the year 1975: *Social Science History* (USA, 1975); *Geschichte und Gesellschaft* (West Germany, 1976); *History Workshop Journal* (UK, 1976); *Social History* (UK, 1976). Along with the *Journal of Social History* (USA) founded in 1967 they represented the new 'historical social science,' complementing the older 'school-forming' reviews such as, above all, *Annales ESC* (France, refounded 1946) and *Past and Present* (UK, 1952).

National Variations and International Circulation of Ideas

The triumph of social history in the 1960s and 1970s was a transnational phenomenon. The themes, questions, and methods were astonishingly similar in different countries; the

international specialist public was interconnected through increased contacts. In many places the attractiveness and legitimacy of new approaches were aided by models coming from other countries. Particularly the French *nouvelle histoire*, often described by others as the *Annales* school, developed into a veritable export hit. Already at the international historians congresses in Paris in 1950 and in Rome in 1955, its French representatives and Italian or English allies very much set the tone (Erdmann, 1987). In the following decades, the international circulation of concepts and approaches took on greater strength through the translation of books. A few historiographic models or theoretical influences (such as for instance the work of Fernand Braudel) became widespread in the countries of southern Europe and South America, while others won international recognition via their reception and dissemination on the North American market.

Yet for all that the national differences remained considerable, even in retrospect and after several decades of approaches and exchanges. The strengths of the French school remained – with a few exceptions – limited to the Middle Ages and the early modern period. Not the genesis of industrial society but the explanation of the revolution of 1789 was, and remains, the dominant theme for French historians. By contrast, in Great Britain, an early market society and 'first industrial nation,' historians gave particular importance to these factors. The central approach which English social historians shared with social reformers and social scientists was however focused on the persistence and dynamism of class society.

It is by no means a coincidence that E.P. Thompson in his pioneering work *The Making of the English Working Class* (1963) made decisive strides for social history in this field. And the historical self-examination in other countries can also – though certainly not entirely – be characterized through central motives in their social development: the United States as an immigration and frontier society, in which ethnic cleavages are given more weight than class conflicts; Sweden with its experiences of mass emigration and social crises at the end of the nineteenth and beginning of the twentieth centuries; and finally Japan, which after World War II looked to describe its latest developments in terms of Marxian-inspired modernization models (Conrad, 1999). The political breaches and catastrophes of the twentieth century also formed the node of the new German social history, which was especially influenced by the political and social history initiated by the 'Bielefeld School' historians. The German *Sonderweg*, the German divergence from the West, and the social conditions for the national-socialist rule were the central preoccupations of a whole generation of historians who broke with the 'historicists' (*see* Historicism) and individualized explanatory models (Kocka, 1999; Welskopp, 1999).

Topics, *Neighbors*, Models

The place of social history in the intellectual landscape of the historical and social sciences of the post-World War II era, can be understood by tracing the main trends with respect to preferred research topics and questions and its interdisciplinary alliances, methods, and explanatory models. These trends were most conspicuous in the period from the late 1950s to the 1970s, which witnessed the most pronounced change toward the 'new' social history. The reorientation effected by the spread of social history is most obvious with respect to the subjects chosen for monographs, in the programs of congresses, or in the contents of major journals. The history of social classes and social stratification, in general, entered into the historical mainstream.

In researching social mobility and standards of life in the past, historians in Europe and North America tended to prolong the prehistory of their contemporary societies into the nineteenth century (and later even further back). Labor history (*see* Labor History) left its subaltern and ideological niche and expanded its focus to the realities of work, family, and everyday life. The economic interests and social position of political actors were taken seriously and entered into the 'social interpretation' of great processes like the American and French revolutions, colonialism and imperialism, the development of political parties and social movements, or the causes of war. The fluctuation of harvests, prices and wages, the ebb and flow of population movements and land use, even microbes, and the climate were considered with growing technical sophistication and by an increasing numbers of historians.

Population history with the more micro-oriented historical demography became a leading sector of the new historiography: migration, demographic behavior, and household structure were reconstructed by large research projects. The Cambridge Group for the History of Population and Social Structure founded in 1964 by Peter Laslett, E.A. Wrigley, and Roger Schofield as well as the historical department of the French *Institut National d'Etudes Demographiques* represented the effort of making history 'scientific,' and influenced similar enterprises in Germany and Austria, the Scandinavian countries, and North America among others. Similar aims were held by historically minded sociologists, political scientists, and economists who joined historians in the United States to create a discussion forum under the heading of 'Social Science History' (with conferences since the 1960s and a journal of the same name since 1975).

The flourishing subfields, each with its own journals, congresses, and experts, read like a repertoire of social history themes (Stearns, 1994): labor, demographic, family, urban, rural, ethnic, women's, and gender histories emerged and became aspects of a more encompassing social history . Internal sequences and echoes were to be observed in the establishment of subdisciplines and the proliferation of new topics: the growing emphasis on mentality, agency, subjectivity, and experience since the late 1970s was itself a response to the establishment of abstract, often quantitative, studies on standard of living, family and demography, social and geographic mobility, or political interest groups. Women's historians criticized the unspoken gender assumptions of much of historical demography and family studies, as well as of the history of labor markets and welfare states. The very meaning of the term 'social' was itself reconceived; it lost its direct association with 'socialist' movements or 'social policy' and embraced, instead, the whole abundance of the life-world. The enlarged thematic spectrum of the Amsterdam-based *International Review of Social History* (1956), the Parisian *Le Mouvement Social* (1960), or the German journal *Archiv fuer Sozialgeschichte* (1961) are examples of this transition, which had gained considerable ground by the mid-1970s.

The shift in interdisciplinary alliances mirrored and underpinned topical interests. The nearest neighbors to history were no longer philology, philosophy, or law, but economics, political science, and sociology. For the French *Annales* School, the close relationship with geography and demography was particularly important. The West German focus on the 'political social history' of the late nineteenth and early twentieth centuries, led to an alliance with historical sociology and political science. Various strands of descriptive, often quantitative, economics, social surveys, and sociography are found among the more practical roots of historians who embarked on studies of living standards, family formation, or business cycles. Equally it should not be forgotten that the enormous growth of sociology in the postwar-era held a particular attraction for historians.

The varieties of social and cultural anthropology or ethnology, as it is called in some countries, served as models for a minority of social historians, especially those working on early modern history. The journal *Comparative Studies in Society and History* (founded in 1958) became an important forum for historically minded anthropologists and anthropologically interested historians and social scientists. The relationship between history and anthropology – a discipline which has also changed dramatically during the last three or four decades – is a good indicator for the underlying change of emphasis from 'society' to 'culture' within social history. Natalie Z. Davis's influential collection of essays *Society and Culture in Early Modern France* (Davis, 1975) or the wide impact of Clifford Geertz's writings, especially his 1973 collection *The Interpretation of Cultures*, are cases in point.

Parallel to these shifts, the protagonists and agents of the new social history reflected on the mechanisms of scientific change as such. What appeared to be happening, under their own eyes, and with their help, in the humanities and social sciences seemed to resemble a 'paradigm shift,' as Thomas S. Kuhn had described it for physics in his influential book *The Structure of Scientific Revolutions* (1962). Notwithstanding Kuhn's own doubts as to whether his model could be applied to the social sciences, the 'paradigm shift' became a battle cry in the nascent struggle to establish social history over and against the history of politics, great men, or ideas. The implications of Kuhn's work for the history of science were also welcomed by social historians. Indeed, the emphasis on social and external factors in the development and application of knowledge clearly corresponded to the efforts of social historians to stress context, interests, and structural constraints when dealing with ideas and ideologies (Appleby et al., 1994).

Although, at the time, many were fascinated by the idea of a 'paradigm shift,' in retrospect we see a more subtly differentiated, less abrupt transition. It is certainly true that in individual national academic traditions there were, in part, intense debates as to the 'right' sort of history. And in most cases a political dimension was also present, in which social history was defined as being more to the left and political history more to the right. However, rather than superseding an old paradigm, social historians could work on several levels (institutional, methodological, and thematic) and go about broadening and innovating their field within quite different time frames. If one sees the success story of social history as a pluralistic project fed from many different sources, it becomes easier to understand its expansion and, its later reorientation in the direction of cultural history. In fact, the many social–political and intra-academic forces, which were involved in the rise of social history, have continued to develop independently and gradually cast doubt upon the plausibility of their own basic assumptions.

These definitional clarifications should not, however, obscure the impact of the new social history on the traditions of historiography. The historicist principles of the historians' craft were challenged by analytical, theory-driven approaches. The borrowing of concepts and even the adaptation of 'middle range theories' (R.K. Merton) as tools in historical research and writing, has become a trademark of social historians as compared to traditional, "narrative historians" (Le Goff and Nora, 1985; Fairburn, 1999). The use of comparative methods gained wide currency (Tilly, 1984). Theories of modernization (*see* Modernization, Sociological Theories of) became more attractive, above all, for historians of the nineteenth and twentieth centuries. Even if the explicit use of theories remained, in general, limited, process-oriented terms such as industrialization, urbanization, secularization, and professionalization became ever more widely used in historiography. And they were by no means limited to social history in the more restricted sense. Modernization, industrial society, even democratization, all were part of the meta-narrative governing a good part of social history writ large – albeit with national differences and often heavy criticism from alternative political currents within social history (see for example Judt, 1979). Yet despite evident tension, the height of the social history wave was marked by a good deal of common ground.

The explanatory models proposed by the 'new' histories of the 1950s, the 1960s, and the 1970s shared the aim of explaining collective behavior and social relations by linking them to the structures of the economy and society. Although most opposed the rigidity of official Marxism–Leninism, many historians conceived of society as an architecture which resembled a vaguely materialist interaction between 'basis' and 'superstructure.' In her work on the French revolution, Lynn Hunt explicitly rejected the widespread partition of monographs in three levels of economy/demography, society, and politics or mentality, by simply turning it on its head (Hunt, 1990: pp. 102–103). Interests, world views, political stances were largely understood as collective responses to objective social positions. Since the 1970s, social history has experienced shifts in its basic assumptions about causality that have led to a much less homogenous situation. But there seems to be a widespread refocusing, first on agency and practices, secondly on meaning and identity, and thirdly on microprocesses.

The Will to Synthesis

The social-historical approach to history set other requirements on the writing of an overall historical account as conventional political history. The narrative structure of political events, the periodization by means of wars or revolutions, and the intentionality of a historiography oriented towards the 'big players' could not be simply transposed on to social history. In this new field, syntheses therefore had to contain – whether one liked it or not – a reflection on the character of 'society.' The will to synthesis is, for this reason, part and parcel of social history's

emphasis on a comprehensive approach to history. Here social history sets itself off most clearly from the study of social and economic phenomena within a context, which continues to be defined in political terms.

The authors of large syntheses in social history are, for that reason, also more or less explicitly protagonists of a 'history of society,' or of a *histoire totale* in the French tradition. Mikhail Rostovtzeff's *Social and Economic History of the Roman Empire* (1926) and Marc Bloch's *Société féodale* (1939–40) are both early and distinguished examples. Fernand Braudel, Eric Hobsbawm, and Hans-Ulrich Wehler emphasized, in their own way, this requirement with monumental general histories. But they could do so only by consciously borrowing concepts and models from the neighboring social sciences and by setting out theoretical considerations on social structure and on the motors of social change. Whether these involved models on temporal and geographic structuressuch as Braudel's, or a flexible use of Marxist theories such as Hobsbawm's, or an explicit use of modernization theories such as Wehler's – in each case this type of general history distinguished itself from the conventional historiography in its explicit theoretical orientation also. Yet a clear difference in the degree to which theory governs the historical narrative or the display of arguments remains between these works and those of historical sociologists such as Immanuel Wallerstein, Theda Skocpol, Charles Tilly, or Michael Mann – authors who, nevertheless, share common interests with the historians.

But also at a more humble geographical and temporal level, social historians have continuously endeavored to reconstruct the object of their investigations, society, as a coherent if multifaceted system, sometimes even in a literary way. Above all, however, they continue writing within their respective national historical frameworks (Wehler, 1987–2008). Often this takes the form of collections of articles in which various authors describe the individual aspects of society (a recent example is Thompson, 1990). Even the short, broad-based handbook giving an overview of the state of research belongs in this category. In part, this reflects the tendency to specific research on social classes and strata which leaves out further societal, cultural, and political contexts (Charle, 1994). Although the emergence of the newer directions of gender, experience, and cultural history has increased the fear that social history would become even more fragmented, José Harris (1993), for example, has explicitly endeavored to integrate these very perspectives into a general historical account.

The Revenge of Success

However, social history's expansion in quantitative scale and conceptual scope was large enough to produce serious side-effects. First, specialization increased dramatically. Greater demand for technical expertise, such as quantification, the creation of such subfields as historical demography, or the tendency of methodological approaches like oral history to take on lives of their own, contributed to the differentiation of the field. Second, the proliferation of topics as well as of local or regional units of analysis deemed worthy of a monograph, concurred to create a very colorful map of approaches and subjects. In the late 1980s and afterwards, representatives of social history looking back on the success story of their field could made out the first signs of self-doubt already present in the second half of the 1970s at the highpoint of social history's intellectual and institutional glory (see contributions in Kocka, 1989). More than any other approach to history, social history gradually came to be marked by fragmentation and dispersion. Third, social history, as a general approach, gained access to other historiographical periods and to other disciplines in the humanities. In literary criticism and modern languages the social history of literature became a trademark in the 1970s and early 1980s and, since then, has met with growing skepticism and disillusionment.

Certainly it must be said that these developments represent a tribute to the success of social history. In the course of differentiation and specialization, the new approaches and subfields which had established themselves under the heading of social history, gradually changed their character and underlying priorities (Burke, 1991). What is often described at the end of the twentieth century as a cultural 'turn,' in fact, emerged over the years. Indeed, disillusionment with the social history of the 1970s can best be understood not as a 'paradigm shift' but rather as an incremental, self-reinforcing, sometimes conflictual transition on different, nonunified levels of historical work: research methods, preferred topics and sources, examples taken from other disciplines, new 'buzz words' and concepts, more hidden understandings of causality, agency, and evolution. Without question, the more recent set of shifts from social history to the 'new cultural history,' makes us think harder about the establishment of social history and its concomitant changes of the societal and political context in earlier decades.

The recent 'cultural turn' can, first of all, be understood immanently, that is, intra-academically. In its various manifestations, social history continued in the tradition of an oppositional approach against the historical mainstream. Small wonder that it has attracted attacks from every new wave of critical and revisionist historians as well as from the revival of older (biographic, narrative) forms of historical writing. The concept of gender has in many countries been at the forefront of debates around structure and agency, macrosociological categories and deconstructivist criticism. Particularly in Germany, a fierce debate with aspects of a generational conflict divided the 'history of society' embodied in the Bielefeld School of *Gesellschaftsgeschichte* (Iggers, 1975; Kocka, 1986; Wehler, 1987–2008) and the 'history of everyday life' (*Alltagsgeschichte*) represented by grassroots history workshops and a number of younger academics at the margin of the profession (Lüdtke, 1995).

Yet one must also consider the external, extra-academic factors which in the last decades have changed the relationship of the social sciences to society. The social and political movements of the postwar years made their mark on social history. Especially in the United States, the expansion of themes and problems in social history since the 1960s had been given a strong push by the corresponding conflicts in US society: the movements of Afro-Americans, of students, of women, and of gays and lesbians added to the traditional input from the workers' movement and radical intellectuals. Since the 1980s, the already proverbial trinity of race, class, and gender reflected these social forces in an academic discourse. In Europe, too, a similar, by no means linear, elective affinity could be observed between social movements (the alternative

left, and the women's, ecological, and peace movements) and fresh ideas in history (gender, everyday, and microhistory).

The 1980s and 1990s experienced a strong move toward independence and pluralization of identity politics and the associated attempts at claiming one's own history for oneself. Taken together, these trends have aided the transition away from a history of anonymous social processes and structures. This reorientation became even stronger with growing critique of the ethnocentric dominance of industrial societies in social history leading up to this time. In recent years, the slow inroads which postcolonial discourses have also made into historical science have, on the one hand, furthered the significance of classical social history, this time in the countries of Asia, Africa, and Latin America. On the other hand, the established concepts of modernization, development, progress, and culture were subject to a thoroughgoing critique and redefinition. Finally, the breakdown of actually existing socialism in 1989/1990 and the resulting political and economic transformation led to reflection on the basics of politics and the economy (Kocka, 2000).

The answers to these challenges and interrogations are by no means clear. The voices which speak of a 'crisis' are not restricted to social history but are directed at the historical sciences, if not the humanities in general. Two trends can be made out: beyond all methodological differences, the self-reflection of the academic historian has moved to center stage. The idea that one can produce reliable knowledge about society – contemporary or past – was in 2000 taken far less for granted than a few decades previously (Bonnell and Hunt, 1999). On the other hand, the historicization of all forms of knowledge has become, as it were, a patent remedy in all debates. In opening up toward this sociocultural direction, it is true that social history may have lost out in unity, perhaps in recognizability, but it has gained in intellectual dynamism.

Editor's Note

Although "social history" as a method of "doing history" has faded as a topic of analysis among professional historians in the past 15 years, social historians continue to produce interesting and informative work. Among the more active of the contemporary social historians is Peter Burke. See his A Social History of Knowledge: From Gutenberg to Diderot (Cambridge: Polity Press, 2000); A Social History of the Media: From Gutenberg to the Internet (with Asa Briggs) (Cambridge: Polity Press, 2009). Google turns up "social histories" of a wide variety of social and cultural phenomena: education in England, the Third Reich, care of the insane, the English novel, oral contraceptives, English music, cricket, post-war Japan, drugs, women in broadcasting, the English countryside, etc.

Social Identity in Social Psychology

This article is a revision of the previous edition article by R. Hardin, volume 11, pp. 7166–7170, © 2001, Elsevier Ltd.

Abstract

In this article different definitions of social identity are outlined that include developmental and sociological approaches. The main focus of the article is on the concept of identity in social psychology and the social identity perspective specifically. The psychological group and social identity processes are outlined along with the conditions that explain which of many identities (self-other similarity, self-stereotyping) will become salient. As part of this endeavor social identification and social identity salience are differentiated and implications for measurement are outlined. It is argued that social identity – the context specific definitions of who 'we' are and what 'we' do – both shape behavior and facilitate behavior change.

Many disciplines in the social and behavioral sciences use the term identity. There is reference to personal identity, social identity, cultural identity, role identity, gender identity, political identity, ethnic identity, and religious identity – to name but a few. In fact based on the social sciences citation index the term identity was listed as a topic 895 times between 1945 and 1970 increasing to 16 125 times between 1991 and 2000 and then to 38 079 times between 2001 and 2010. There is sustained and growing interest in the identity construct. This interest reflects the value and importance of people's group memberships (culture, gender, religion) in explaining phenomena of interest. The growing study of identity also may reflect the availability of instruments to measure the construct in valid and reliable ways. It is also possible that interest reflects a move away from the group (and associated identities) being viewed through a prism of *anticollectivism* – where groups were sidelined because they were considered somehow flawed or inherently inferior to individual understanding (see Reicher et al., 2012 for a recent discussion). For a long time, groups and associated identity have been associated with more primitive 'tribal' psychology where rationality is lost to the emotion of a crowd or mindless conformity to the 'other.' More recently, the group and 'identity' are recognized being important because such processes define standards and shape behavior – what is considered (in)appropriate, just and 'right.' Identity processes are also a vehicle for social change enabling the powerless to be more powerful in addressing inequality and social justice through acting together.

How is identity defined? What is the connection between sociological groups (gender, ethnicity) and identification? Why are these ideas important for the social and behavioral sciences? How is identity measured? Answering these kinds of questions (at least briefly) is the focus of the rest of this article. The article also is framed by the subdiscipline of social psychology and, in particular, explores and highlights social identity as understood within social identity theory and self-categorization theory; often referred to as the social identity perspective (Turner and Reynolds, 2001).

How Is Identity Defined?

The term identity comes from the Latin noun *identitas*, where *tatis* is a derivation of the adjective *idem*, which means 'the same.' There is a focus on sharing a degree of sameness with others on a particular dimension and in order for such sameness to be established comparison is necessary. To complicate matters further the term identity is not used to mean the same thing within psychology or across the social and behavioral sciences. Different literature have used the term in different ways. Even when it comes to use of the term social identity there are divergent meanings, each embedded in particular theoretical frameworks and literatures (e.g., see Brewer, 2001; Deaux, 1993).

Erikson one of the earliest psychologists interested in identity, highlighted two types of identity – ego identity and cultural or social identity. Ego identity refers to a conscious sense of self as unique as well as continuity of experience. A strong sense of self is argued to emerge during adolescence and is central to well-being. One way to think about social identity within this framework is that it captures the extent to which there is a supportive community that validates the identity and gives it strength (e.g., "greater validation of social identity can nurture ego identity," Côté and Levine, 2002: p. 94). More precisely, Erikson argues that "[Ego identity's] most obvious concomitants are a feeling of being at home in one's body, a sense of 'knowing where one is going,' and an inner assuredness of anticipated recognition from those who count" (Erikson, 1968: p. 165).

There is also work on culture and social representations that is related to shaping a sense of self and identity. Being a member of a community means that people come to share the same knowledge, beliefs, theories, conventions, and norms, which give meaning to the environment and guide practices and actions. A common reality of stereotypes, attitudes, opinions, and categorizations is constructed and shared through collective activities (e.g., Augoustinos and Walker, 1995; Chryssochoou, 2004). Such processes underpin the formation of people's 'distal' knowledge, expectations, and theories about the social world and themselves as a function of being a member of a particular 'community' of interacting individuals.

Symbolic interactionism and socialization are central to explaining how the individual becomes shaped by, and attuned to, the social patterns and regularities of their cultural community. There is a trajectory of work through Cooley (1902/1922) and Mead (1934), in particular, where others'

perceptions and reactions are argued to shape one's self-view in a dynamic way. These ideas form the basis of the way identity is understood in sociology where the formation of social identity includes the reflected appraisals of others and others expectations. A generalized conception of one's own self develops through experience and observations of how others act toward the self (the so-called 'looking' glass self). The self is social or public in that it contains the internalized reactions, expectations, and judgments of others (e.g., Turner and Onorato, 1999; Stryker and Statham, 1985). The person enacts these internalized reactions conforming to norms in order to meet others' expectations and achieve the desired outcomes that such conformity affords (e.g., Thoits and Virshup, 1997). In this tradition social identity is an attempt to present the desired views of others as well as define the self to oneself (Deaux and Burke, 2010). The focus in the symbolic interactionist perspective (and related work) is on how the mind is socialized and becomes a reflective object of itself (see Turner and Onorato, 1999 for a more detailed discussion).

In summary, then, the 'social' in identity in the developmental approach, social representations, and sociological literatures refer to others in the environment who impact on the person and the development of self-construal. Identity is self-knowledge gained through experience and reflected appraisals. In sociology there is also an explicit interest in role of groups and socialization of social norms – this work explicitly connects social structure and normative societal or cultural knowledge to explanations of individual behavior. As is outline in more detail in the next section, the psychological group along with a different understanding of social identity may be informative in understanding these processes.

What Is the Connection between Groups and Identification?

In social psychology another layer is added to these understandings of identity. A person may internalize the reflected appraisals of others and the norms and scripts associated with a particular role but not psychologically identify as a member of a particular group in a given situation – 'mothers,' 'social psychologists,' or 'Australians.' As Turner (2000) argues "making a distinction between peoples' relatively stable identifications with particular groups and roles and the salience of any social identity in a specific situation is an important one" (p. 342).

Social identity theory and self-categorization theory focus on the psychological salience of group membership. Self-categorization theory first and foremost is a theory of *psychological* group membership (when is a group a 'group'?). The theory suggests that individuals can view themselves in terms of idiosyncratic personal attributes (e.g., a personal identity) or in terms of social categories (e.g., social identities, such as a social psychologist or an Australian). The concept of personal identity or the personal self ('I') is used to describe situations where individuals perceive themselves to be distinct and different from others (that are available for comparison) and social identity or the social self ('we') refers to an individual's "knowledge that he [or she] belongs to certain groups together with some emotional and value significance to him [or her] of the group membership" (Tajfel, 1972: p. 31).

Importantly, the term social identity refers to psychological groups where an individual perceives him- or herself as being a member because the group is self-relevant and self-defining (Turner, 1982, 1985). Turner (1984) hypothesized that as people defined themselves and others as members of the same category, they would self-stereotype in relation to the category and tend to see themselves as more alike in terms of the defining attributes of the category. This process is referred to as depersonalization. It was argued that it is "the cognitive redefinition of the self – from unique attributes and individual differences to shared social category memberships and associated stereotypes – that mediates group behaviour" (Turner, 1984: p. 528).

It is also recognized that the self is hierarchically organized and can be defined in ways that are more or less inclusive of others (as similar to self) at the individual, subgroup, and superordinate levels. In this exploration of levels of self-categorization, all the different aspects of human experience (as an individual 'I' and group member 'we') are addressed providing a more integrated view of the whole person. Using the same terminology as Kluckhohn and Murray (1953), it is possible to explain how the individual person is like no other person, how the individual person is like some other persons, and how the individual person is like all other persons.

Fundamental SCT research suggests people will only act in the interests of a group to the extent that they see that group as self-defining in a given context (Turner et al., 1994; Oakes et al., 1994). From this perspective, then, a critical question is what determines which identity (and its associated content) will become relevant and meaningful in a particular situation. In self-categorization theory, it is argued that a particular self-categorization and associated norms, beliefs, and behaviors are an outcome of the dynamic interaction between perceiver readiness factors and comparative and normative fit factors. It is the resulting salient self-categorization or identity, that may be as an individual or group member, that is informative in understanding and explaining one's behavior in a given situation.

Perceiver readiness builds on Bruner's (1957) notion of accessibility and relates to the accessibility of particular ways of categorizing based on the perceivers' expectations, motives, values, and goals (Oakes et al., 1994: p. 199). Turner (1987) argues that the "the centrality and evaluative importance of a group membership in self-definition, is a major determinant of accessibility" (p. 55). For example, highly prejudiced people, for whom being 'white' could be an important aspect of their self-definition, may be more ready to categorize stimuli (e.g., a meeting where Anglo-Australians and Indigenous Australians are present) in racial terms. Perceiver readiness can be viewed as 'tuning' the perceiver to particular features in the stimulus environment or social context (Swann and Seyle, 2005).

Readiness is not the only consideration in explaining salience. There must be evidence in the situation that sustains such a categorization. Perceiver readiness and the perceived features of the stimulus environment interact to produce

context-specific categorization. The *meta*-contrast principle is the basis of comparative fit (Turner, 1985). This principle states that in a given situation, stimuli will be categorized as the same when the average differences perceived between them (intraclass differences) are less than the differences between them and other stimuli (interclass differences) within the comparative context.

Categories are formed through a context-specific assessment of similarity and difference. For example, an individual would self-categorize more as a clinical psychologist ('us') rather than individual academic ('I') at a Departmental staff meeting, to the extent that during discussion, the differences between the person and other clinical psychologists were perceived to be less than the differences between clinical psychologists and personality psychologists in that particular social context (e.g., discussions on a new appointment in the Department). Based on the principles of comparative fit, in another situation when social psychologists were included in the frame of reference because say they started to make a pitch for a social academic to fill the new position, clinical and personality psychologists could be seen as more similar ('us') and unified in comparison to the social group ('them'; see Haslam and Turner, 1992; Haslam et al., 1992).

Also impressions of one's own sense of self as a unique and distinct individual ('who am I') are viewed as an act of categorization. An individual may be perceived as outgoing or caring to the extent that the behavioral variability displayed by the person in relation to this characteristic across time and occasions, was less than the variability on this dimension between the individual and other individuals available for comparison (also see Plaks et al., 2003). The formation of a person category follows the same process as the formation of a social category (Mavor, 2004; Oakes, 1987; Oakes et al., 1994; Reynolds and Oakes, 2000).

However, to categorize oneself and others as clinical and personality psychologists or as outgoing or caring, there must not only be similarities within and differences between the stimuli, but these must be in the direction that makes sense for the perceiver on the relevant dimensions of comparison. So there is a content as well as a structural dimension to categorization. The similarities among clinical psychologists (and differences from social psychologists) must make sense based on people's normative expectations about these groups. Normative fit relates to the content dimension, the direction or meaning of the categorization in a particular social environment (see Oakes, 1987).

In summary, the focus for these social psychological theories is on psychological group memberships and social identity – the term in-group is used to describe a group where the norms, values, and beliefs that define the group are internalized and become self-defining in a given context. The theories, knowledge, and normative understandings one has about the world that are shaped by societal position, social roles, and social relations and culture, are only one aspect in explaining social identity salience. It is also necessary to consider the immediate context where the emergent self-categorization or identity that drives behavior will be an outcome of the interaction between 'distal' knowledge (perceiver readiness) and features of the situation (comparative and normative fit).

Why Are These Ideas Important for the Social and Behavioral Sciences?

"A group or role may be chronically self-defining across time, but its influence on behavior is a function of its immediate prepotence in self-perception, which reflects varying motives, goals and circumstances" (Turner, 2000: p. 343). This statement highlights why the social identity concept properly understood is important for the social and behavioral sciences. In the Lewinian tradition, social identity recognizes the group and emergent norms as being important in explaining behavior but also provides new avenues to understanding behavior change (see Lewin, 1951; Reynolds et al., 2010, 2014; Reynolds and Turner, 2006).

Given the importance of this point it is worthwhile explaining in more detail the self-categorization theory argument. In explaining group behavior Turner (e.g., 1987) argues that (1) individuals define themselves as similar to others as a member of the same social category (similar perceivers, in a similar position experiencing the same environment), (2) they learn or develop the appropriate, expected, desirable behaviors that are related to category membership and differentiate it from other categories (a sense of 'us'), (3) they assign the norms and attributes of the category to themselves (internalization) through processes of self-stereotyping, and (4) thus their attitudes, emotions, and behaviors become normative as their category membership becomes salient.

These ideas were extended and further investigated (Turner, 1987, 1991) to show that it is through agreement with other group members 'like us' that one comes to feel one's views are valid, correct, and right. When similar others see the world in the same way this gives us confidence in our own responses. Because other in-group members are viewed as similar to oneself, they become a valid source of information and a testing ground for one's own views on relevant dimensions. It is through social identification and associated social influence that others 'like us' come to play an important role in establishing one's own views, the certainty of such views, and their transmission within the group.

It is argued that it is only within a shared in-group framework where there is a shared social identity that differences in perspective (e.g., criticism, new ideas, deviance) can be resolved through discussion, clarification, and mutual influence. Through these processes in-group members can shape each others' norms, values, and beliefs in significant ways (re)defining 'who we are' and 'what we do.' As different people come to be defined as similar to oneself, they offer new opportunities for social influence and the potential for one's theories, expectations, and beliefs about oneself and the world can change. In a more general sense, though, it is through social identity and the construction of definitions of 'who we are' and 'who we are not' – of making particular definitions of who 'we' are salient and prepotent – that explains how behaviors can become consensualized and transformed into coordinated action.

How Is Identity Measured?

An important distinction has been made between people's relatively stable social identification with particular groups and

social identity salience in a specific situation. Those roles or groups that may be chronically self-defining across time need to be salient in the situation to affect behavior. Postmes et al. (2012) recently argue that social identification is not extensively discussed in either social identity theory or self-categorization theory. The focus of these theories is on recognizing and understanding the emergence of a social identity and its consequences. Social identity is understood as an entity that has meaning psychologically because of its defining characteristics, norms, and relationship with out-groups. Social identity salience refers to how psychologically operative the social identity is in the current context and is important in explaining behavior in a given situation.

In contrast, social identification can be understood as a person's relationship to that entity. Social identification can be thought of as an individual difference measure indicating how important and valued a particular group membership is to self-definition. In self-categorization theory terms it indicates, in part, a person's readiness to see themselves in terms of a particular social category. The salience and internalization of a particular group membership can affect one's readiness to perceive oneself in terms of the particular group in the future (see McGarty, 1999 for further elaboration).

The distinction between social identification and social identity also is important in terms of understanding the 'meaning' or content that defines 'us' in a given situation. Measures of social identification do not (typically) clarify the meaning of the social identity. Two people could indicate to the same degree that being an Australian is important to their identity, they feel pleased to be an Australian, and feel strong ties with other Australians but yet the meaning of the category (the dimensions on which they are self-stereotyping) is fundamentally different. Social identity salience, on the other hand, leads to increased uniformity in self-stereotyping among in-group members as the process of salience itself serves to clarify and consensualize 'meaning' or content. When a social identity becomes salient it will involve comparison with others and categorization of similarity and difference. A shared representation of 'us' and 'them' is likely to emerge as well as clarify of who 'we' are in this context.

Most of the measures that have emerged over recent years concern social identification. During the 1980s and 1990s, there was a focus on unidimensional measures of identification (Haslam, 2004; for a review). Doosje et al. (1995), for example, developed a four-item scale with items covering cognitive (a person's knowledge or awareness of being a member of a particular group; 'I identify with members of (Group X),' 'I see myself as a member of (Group X)'), affective (a person's feeling of affective commitment to the group; 'I feel strong ties to member of (Group X)'), and evaluative (a person's sense of group-based positivity; 'I am pleased to be a member of (Group X)') components of identification. Multidimensional scales started to emerge at the end of the 1990s and have been expanding in number (e.g., Cameron, 2004; Ellemers et al., 1999; Leach et al., 2008; Phinney, 1992; Roccas et al., 2008; Sellers et al., 1998).

Roccas et al. (2008) propose four modes of identification that are conceptually distinct – importance (how much I view the group as part of who I am), commitment (how much I want to benefit the group), superiority (how much I view my group as superior to other groups), and deference (how much I honor, revere, and submit to the group's norms, symbols, and leaders). Superiority is an example where an aspect of social identification moves away from one's relationship to the entity to a belief about the entity itself – it comprises information about social position or group beliefs. Seller et al. (1998) do the same with their Ideology scale that forms part of the Multidimensional Model of Racial Identity measurement.

Postmes et al. (2012) have recently argued that there are advantages in use of single-item measures of social identification. With a single item there is clarity of what is being measured and transparency. It is also efficient to measure constructs of interest with as few items as is possible. Furthermore, short scales can be just as valid and reliable as multi-item and multidimensional measures in particular when the construct under investigation is clearly defined and relatively homogeneous (e.g., Burisch, 1984; Loo and Kelts, 1998). Postmes et al. compared the single item 'I identify with my group' to other multidimensional and single-item measures and found the single item was reliable. This item alone captured much of the concept of social identification.

The measurement of social identity has attracted less attention among researchers (perhaps because of confusion with social identification). Social identity salience (a social identity that is activated or deployed at a given point in time) should be revealed by self-stereotyping in relation to the defining features of the in-group in comparison to the comparison group/s (e.g., women compared to men). Hogg and Turner (1987), for example, showed that when people were organized into mixed-sex groups (men and women) or same-sex groups (men only or women only), individuals were more likely to define themselves in terms of gender and to accentuate their similarity to those of the same gender in the mixed-sex settings as opposed to when only men or women were present (see also Oakes et al., 1991; Onorato and Turner, 2004).

In addition, salience means that there should be greater consensus on the defining content of what it means to be a group member. Along these lines, Haslam et al. (1999) asked participants to reflect on their social category membership as Australians (social identity condition) or to focus on their uniqueness from others (personal identity condition) and completed a checklist identifying words typical of people from Australia before and after a group interaction phase. In the social identity condition (and especially postinteraction), there was greater consensus on the attributes that defined the category of Australian.

When social identity is salient there should be a sense of self-other similarity within the in-group and self-other difference with respect to the comparison group/s. These similarity aspects of social identity salience can then be captured by measures such as 'How similar you think you are to other members of Group X?'; 'How much do you think you have in common with members of Group X?'; 'How similar do you think your values are to members of Group X?'; 'How similar do you think you are to members of Group Y?'; 'How similar do you think members of Group Y are to each other?'; 'How much do you think members of Group X

are similar to one another?'; 'How representative do you think you are of Group X?'; 'How much do you think members of Group X will agree?'

Close inspection of the measurement of social identification and social identity and its salience helps to clarify how these concepts are being defined and used. The development of measurement tools serves to help further clarify these constructs and investigate when and how these concepts are useful in explaining behavior and behavior change.

Conclusion

In this article different definitions of social identity have been outlined that include more developmental and sociological approaches where the focus is on the formation of social identity and its importance for the individual. There is a vast and vibrant exploration of these concepts in these areas that has only really been touched on briefly. The focus of the article has been on social psychology and the social identity perspective specifically. From this perspective the preoccupation is on explaining which of the many group memberships will emerge and become important in predicting behavior in a given situation and its consequences. As part of this endeavor it has been important to differentiate social identification from social identity and its salience. This distinction has implications for measurement. It has been argued that it is social identity salience – the context-specific definitions of who 'we' are and what 'we' do – that both shape behavior and facilitate behavior change.

Abstract

Social identities are definitions of self based on claimed membership in a social category. They incorporate not only cognitive meanings but also emotional significance and motivational implications. Important features of social identification include their multiplicity, the possibilities of change over time, and the range of behavioral consequences that are linked to the endorsement of an identity. Additionally, social identities serve as an important conceptual link between individual psychological processes and the situational and structural features of society.

Social identities are conceptual markers of categorical membership. They define the boundaries (however fuzzy) of a grouping of people and they implicate characteristics that members of that grouping are believed to share. Social identities not only provide cognitive meaning for those who hold them, but they also imply emotional investment in a position and the potential to take actions that are consequential for the identity. Although social identities may emerge from and be reflective of interaction with the group of people who share the identity, they do not require direct contact or interchange with all others who share the category membership. That is, a social identity is fundamentally a self-descriptive psychological position rather than a specific interacting group. Examples of social identities include gender, ethnicity, sexual orientation, nationality, religion, political party, and occupation. In each case, the social identity is a part of self-definition for the person who claims it.

The concept of social identity is ubiquitous in contemporary social science and in popular discourse as well. Within the social and behavioral sciences, theories and investigations of social identity are common to sociology, psychology, and political science, and have emerged in other disciplines, such as economics, as well. 'Identity politics' take the scholarly concept to the streets, grounding it in the day's diversity and civil rights debates while perhaps complicating its scholarly usage. Given this broad sweep, it is perhaps not surprising that some writers have advocated an elimination of social identity from the scholarly lexicon. However, the widespread use of the term suggests that the concept of social identity captures some important elements of human behavior that need more rather than less engagement.

Consider some of the ways in which social identity pervades the analysis of political and social behavior. Immigration debates often highlight issues of national and ethnic identity: for example, should immigrants reject the ethnic identity associated with their country of origin and replace it with the national identity of the new country? Perceived threats to religious identity are often at the heart of prolonged intergroup conflict. Political movements gain strength as more people identify themselves as feminists or peace activists or environmental Greens. In each case, the group label is not simply a way to make distinctions between groups of people, but it is a basis for those who claim the label as self-descriptive to define themselves, their agenda, and their mode of interaction with others.

Numerous theories of social identity have emerged over the years, ever since early scholars such as George Herbert Mead and William James staked out the territory a century ago. Not surprisingly, these theories and investigations reflect disciplinary predilections as well as salient social issues. Sociologists are likely to use symbolic interaction theory as a touchstone, exemplified by the work in a line that extends from Stryker (1980) to Burke and Stets (2009), with many points in between. Psychologists are more apt to turn to Tajfel's (1981) social identity theory and the subsequent developments of self-categorization theory (Turner et al., 1987). At the same time, the phenomena and concepts at issue do not adhere to strict disciplinary boundaries, with psychological process often of interest to sociologists and political scientists and psychologists paying attention to groups and social systems. This disciplinary fluidity reflects the pivotal role that social identity plays in thinking about social behavior, acting as the intermediate link between micro-level psychological processes and macro-level contextual and structural features. For many, the challenge is to integrate the insights from these multiple orientations in a way that can capture both individual and collective processes (Deaux and Martin, 2003; Jenkins, 2004).

My agenda here is not to argue for a particular identity or to sort out theoretical intricacies among theories. Rather, I take as a starting point the validity of social identity as concept and social psychological reality and I focus on four key principles that characterize these identities.

1. Social identities, as a form of self-definition and categorical membership, are inevitably related to but not identical in meaning or function with the categorizations used by others.
2. People typically have multiple social identities that they consider important to their self-definition, which can overlap or be independent of one another, and can be used in different circumstances.
3. Social identities are not static categories but are dynamic entities subject to change over time.
4. Social identities have motivational properties and social consequences.

Each of these principles is developed in more detail in what follows.

Insider and Outsider Perspectives on Social Identities

The categories that serve as the basis for social identities are social constructions that are used in society to create meaningful commonalities and distinctions among people. As such, the meanings associated with any specific category, for example, Australian, Buddhist, or Tea Party member, are to some degree shared by the person who identifies with the category and an observer who is describing someone in that category. Both perspectives draw from common cultural representations to define the identity category; moreover, even the choice of a particular social identity is shaped to a large degree by the set of social categories that is available in a given society at a given time.

Visibility of category markers, for example, skin color, facial features, or religious dress, increases the likelihood that a particular category will be prominent in the repertoire of the holder of the identity as well as the society at large. Further, to the extent that a particular category is salient, it is more likely to shape social interactions; these experiences shared by actor and observer in turn can create more commonality of meaning between the two perspectives. Phenotypic prototypicality, that is, the degree to which a person's physical appearance is considered to be highly representative of the group as a whole, can influence judgments of the importance of racial/ethnic identity, both by observers and by those holding the identity (Wilkins et al., 2010). African-Americans whose faces are considered to be more prototypical of their ethnic group, for example, are believed to be more strongly identified with their ethnic group. Similarly, African-Americans themselves identify more strongly with their ethnic group when their facial features are more prototypically African-American. We can assume that for these visibly categorized people, ethnic identity is more salient in daily interactions than it is for those whose racial markings are less obvious; in turn, greater exercise could result in more centrality accorded to the identity, relative to other identities that might be available but are less often engaged.

Although the visibility of category markers may increase the likelihood that the insider and outsider views of a social identity are similar, possibilities for divergent views abound. A second-generation Asian-American may resent assumptions that their Asian identity is dominant, for example, and questions such as 'Where are you from?' or 'Do you speak English?' can constitute threats to a strongly held identity as an American citizen (Cheryan and Monin, 2005; Wang et al., 2012). Although the inquiry may seem harmless to the asker, targets of the question can be offended and angered by the identity assumptions implied in the question.

Differences between the 'inside' and the 'outside' views of social identity are due in part to the different purposes that they serve. From the outside, a social category is a convenient and indeed unavoidable method of classification, a censuslike means of simplifying the social world by creating a relatively limited set of concepts to deal with a broad array of people and behavior. These beliefs are, in essence, the stereotypes that members of a community to a large degree share. They are a shorthand that sets a priority on simplicity, lack of ambiguity, and low variation within the category. Whereas social categories serve reductionist purposes from the outside, a social identity can be considerably more complex from the insider's perspective, both in the functions it serves and in the range of meaning associated with category membership.

Categorization and self-definition are the first step in social identification, but not the only basis for characterizing and differentiating social identities (Ashmore et al., 2004). As a consequence, people who nominally share the same categorical label, such as man, Moroccan, or Mormon, will not always act the same. Perhaps the best-documented dimension of identity is self-rated importance: how central or significant or strongly held is a social identity for the person? Not all people who claim a social identity are equally committed to that identity; it is the variations in rated importance that help us understand why members of the same category do not necessarily act the same way in what seem to be identity-relevant circumstances. The more strongly a social identity is endorsed, the more likely is the person to interpret events in terms of the socially defined group, to take action on behalf of the group, and to be threatened by situations that challenge the social identity. Beyond the importance dimension, social identities vary in other ways as well. Identities can be more or less embedded in social networks, more or less expressed in behavioral acts, and defined by a wide assortment and not necessarily shared web of experience and meaning. These psychologically based dimensions of difference can be critical in understanding if, when, and how people who have a particular social identity will take action relevant to that identity category.

Differences in meanings and functions of social identities between insider and the outsider views often lead to faulty assumptions. As noted earlier, the observer who infers nationality on the basis of Asian physical features is effectively denying an identity that the second-generation American citizen may hold strongly. Similarly, the observer who imputes meaning to a category that the identity holder does not share (e.g., all feminists burn their bras, all gays are promiscuous) creates problems for social interactions between the two. And yet, although insider and outsider views may be different, they are not completely independent of one another. Indeed, a person's perception of how others view their social group can be a source of self-definition (the classic image of a 'looking glass self').

When insider and outsider views are discrepant, the person whose identity is in question typically has the option of acting in accord with the views of others or diverging from that view to be more consistent with his or her own views (Barreto and Ellemers, 2003). Agreement with the beliefs of others might be chosen for instrumental reasons, for example some personal gain to be experienced from going along with the suppositions or some embarrassment or cost likely to be experienced if one were to diverge. Thus, pretending to be a strong organizational supporter may be preferable to being socially shunted, or staying 'in the closet' may at least temporarily avert criticism or rejection for the gay person interacting with friends or family who are unaware of the sexual preferences.

Choosing to be consistent with one's own identity classification and definition depends on the strength and importance of an identity to its holder, as well as on the circumstances in which identity expression takes place. To the extent that the views of others are unfavorable, as is often the case for minority and stigmatized groups in society, people are less prone to act

in accord with those views. In such instances, the 'looking glass self' may not be an appropriate metaphor, as members of the devalued groups will disregard the views of others in service of maintaining and promoting self-esteem (e.g., Perkins et al., in press).

In sum, the apparent simplicity of social categories and the seeming inevitability of their use can mask the complexity of their construction and the variability of their usage. Further, while insider and outsider views of a social identity category may overlap and interact, the analysis of social identity and its behavioral outcomes requires maintaining a clear distinction between the two.

Multiplicity of Identities

Social identities are defined in terms of identification with and/or membership in specific social groups and categories. Given the complexity of contemporary society, people are likely to have more than one meaningful identity, an assumption that dates back nearly a century to the influential theorizing of the sociologist George Herbert Mead and the psychologist William James. Multiple categories of group membership are instantiated in census reports and survey structures as well as reflected in common discourse. Thus, people can be characterized in terms of their gender, their ethnic or national group, occupation, sexual preference, age, or political position, and numerous other often-used bases of demarcation. Not everyone thinks of him- or herself in terms of each of these possible membership categories; yet most people readily claim to identify with several of them and see these identities as having distinctive features.

Accepting the assumption of multiplicity raises questions as to how various identities might be combined and/or integrated. From the outsider perspective, two or more categories can be combined to create an analytic subcategory, for example, African-American men with college degrees, which in turn can be linked to outcomes of interest, for example, occupational attainment. This approach, however, does not speak directly to the insider process of social identity construction. A more qualitative approach to multiple identities, often represented by the term *intersectionality*, puts its emphasis on the unique characteristics of the combination of identity categories (Crenshaw, 1991; Stewart and McDermott, 2004). By this line of thinking, the juxtaposition of, for example, gender and ethnicity creates emergent properties that are not part of either constituent category on its own. Thus, the experience of being a Latina cannot be fully described by adding together typical descriptors of 'woman' and 'Latino.' Similarly, Muslim women have experiences that are unique to the category combination, rather than determined by religion or gender alone (Deaux and Greenwood, 2013).

Multiplicity of identity and the possible forms of integration are central concerns in the immigration debates, typically focusing on whether identities such as ethnicity or religion can effectively coexist with a national identity, or, alternatively, whether the former must be jettisoned and replaced by a primary identification with the nation state. From a psychological perspective, the concept of biculturalism or multiculturalism is widely accepted, with current discussions centering not on whether a person is capable of holding two or more identities but rather in detailing the various forms that such combinations might take and the social conditions that influence the choices that people are likely to make (Benet-Martínez, 2012; Berry, 1990; Deaux and Verkuyten, 2014; Hong et al., 2000; LaFromboise et al., 1993). In the political realm, in contrast, the possibility of combining identities is often questioned or emphatically denied. In Europe, opponents of multiculturalism often claim that being Muslim is incompatible with a national identification; in the United States, the argument is that being American requires letting go of Latino culture and Spanish language. In part, these different positions reflect the insider–outsider distinction noted earlier, as outsiders simplify the categorization while insiders experience greater complexity and variation. Beyond that distinction, however, the highly charged environment of immigration debates today sets an agenda that is quite detached from the relevant scientific data.

Another question raised by the assumption of multiple identities is how to predict which identities might be more salient and more likely to guide behavior on what occasions. In other words, if one has a choice to make when presenting the self in social interactions, what guides that choice? Several factors contribute to the selection. First, an identity is more likely to guide behavior if it is more important to the individual (Wiley and Deaux, 2011); for example, a strongly identified feminist is likely to view many situations in terms of their possibilities for expressing feminist thought and action, whereas a less strongly identified person might be more selective in the occasions on which feminism is expressed. Immediate circumstances are a second influential factor: similarity of a particular identity with the perceptions of others in the situation (termed the comparative fit) or the normative demands of a situation can increase the salience of a particular identity such that most people who have the relevant identity will act in ways consistent with it. (Think of students and professors in a classroom, or those with a religious identity while in a church, synagogue, or mosque.) The power of situational cues to influence identity salience and in turn affect behavior is dramatically seen in the classic work of Shih et al. (1999), wherein Asian-American women performed better on a math test when their Asian identity was salient and worse when their female identity was salient, consistent with stereotypes about the superior or inferior mathematical skills of Asians and women, respectively.

A third consideration in the choice of identity expression is the strategic concerns of the individual, taking into account the views of the perceived audience and motivated by specific interaction goals, such as being recognized or accepted by the group. From this perspective, people are actors who can consciously (and perhaps unconsciously as well) choose what aspect of themselves to present and will vary their choices depending on their own objectives and their reading of the audience they are facing (Klein et al., 2007; Wiley and Deaux, 2011). As an example, when an Asian-American student is asked by a white investigator whether he or she speaks English, thus questioning the student's American identity, the student will, when given the opportunity, indicate a preference for American over Asian food and recall more American TV shows as an index of their cultural

knowledge (Cheryan and Monin, 2005; Guendelman et al., 2011). In other cases, a person may avoid presenting an identity, assuming the audience will not accept them in that guise, as when a Dominican American immigrant says, "I never say I'm American just because people are not going to believe you are American when you have this whole Spanish look" (Itzigsohn, 2009: p. 133).

The reality of multiple audiences and a charged political atmosphere that intensifies either-or thinking makes the choices of those who value multiple identities much more difficult. Presentational choices made with one audience in mind may cause difficulties when another audience becomes salient and conflict may be avoided only in places where other bicultural people confirm a shared, if complex, reality.

Changes in Social Identities

Some ascribed identity categories, such as gender or race, are generally constant across time, but many other social identities can and do change over the life course. At the most basic level of category inclusion, a person can shift from being a student to being a professor, or from being married to divorced. People also change occupations, join political movements, or assume a new nationality after immigration. These are the most obvious forms of identity change, in which the basic set of memberships is added to or subtracted from. Yet, because social identities are best conceived as having multiple defining elements (Ashmore et al., 2004), all identities can change in ways that are highly significant to the individual but perhaps not evident to the casual observer who uses categorical membership alone to characterize identity.

As one example, consider the shifting meanings – and labels – that have been used by Americans of African descent to describe themselves and to be described by others over the course of the US history. As Philogène (2001) has detailed, the terminology has evolved from Slave to Colored to Negro, terms that all originated in the dominant White discourse, to more recent usage of the terms Black and African-American. Moreover, these changes in social identity were not simply labels, but also involved reformulations of the meanings associated with category membership. Whereas Black was an identity based on racial dichotomization in the United States, that is, Black vs White, the connotations of African-American gave cultural meaning to the identity category and put the group on a par with other ethnically defined groups in the United States.

Why might a person's social identity change, either by shifts in subjective importance or meaning or in more fundamental ways such as the incorporation or rejection of an entire definitional category? Both internal and external pressures can be the impetus for change. Subjective goals and aspirations often lead a person to adopt new social identities, as an occupation or activity group becomes definitional and shared with similar others; conversely, shifting interests can lead to elimination of a previously held identity. Increases in the importance or priority of one identity can decrease the importance of another (although no upper limit on the number of social identities has been established). The acquisition of new information can change the meanings associated with an identity. External forces are also influential. Opportunity structures may change so as to allow a person to take on an identity previously not available, as when women are allowed in the military or immigrants take up residence in a new country. Experiences of discrimination can intensify a person's identification with the stigmatized category (supported by research on what has been termed the rejection-identification hypothesis), as well as change or add to the meaning of the identity itself. Alternatively, perceived loss of status among members of a high-status group can create or intensify identification with a social identity not previously acknowledged. An example of the latter process can be found in the increasing importance attached to white identity among some groups in the United States in the face of changing demographics (Knowles and Peng, 2005; McDermott and Samson, 2005).

More longitudinal work is needed to clarify the parameters of identity change, particularly in the subjective elements that vary among people who share a common category. The evidence is already quite clear, however, that social identities are dynamic rather than static in nature, and that recognition of the possibilities for change is essential to understanding the links between identities and subsequent actions.

Social Identity: Actions, Reactions, and Consequences

Social identities are more than self-descriptive characterizations and a means of positioning oneself in the larger social world. Their considerable importance as a conceptual tool for social scientists stems from their motivational properties, leading to predictable actions and reactions that serve and further a person's goals and a group's impact. People whose social identities are threatened in some way have emotional reactions, engage in cognitive thought processes, and often take actions to avoid or to challenge the threat. People who are stigmatized or devalued because of their group membership often perform less effectively in circumstances where they are being tested. Alternatively, unfair treatment based on group membership can promote collective action on behalf of the group to improve conditions and redress injustice.

Not all who characterize themselves in terms of a particular identity will necessarily take the same actions, nor even take any action at all. The most reliable single indicator of the likelihood of action, involvement, or emotional and cognitive reactions in identity-relevant conditions is the subjective importance of the identity (although more fine-grained predictions are possible when the assessment of self-investment in an identity is further dimensionalized, see Leach et al., 2008). Subjective importance of an identity as a determinant is not independent of contextual influences, of course. Further, because people typically have multiple identities, some of which are equally important to them, particular characteristics of the audience may lead to the selection of one identity over another (Wiley and Deaux, 2011). Turkish/Dutch biculturals, for example, have been shown to emphasize a Turkish identity to a Turkish audience, while presenting a Dutch face to a Dutch audience (Barreto et al., 2003). Such alterations in performance should not be taken as evidence of inconsistency or identity confusion, but rather a demonstration of motivated selective identity enactment.

Areas in which social identities have consequences are extensive, covering a range of individual, intragroup, and intergroup domains. Here I consider just two from this broad array: academic performance under conditions of threat to a social identity; and collective action as both cause and consequence of social identity.

Social Identity and Stereotype Threat

People are not oblivious to the negative views of others. When those negative views are associated with a social category with which one identifies, performance in domain-relevant arenas can be affected, to the detriment of the person holding that identity. This phenomenon, known as stereotype threat (Steele, 2010), has been demonstrated over a variety of identity categories, including race, gender, age, and social class. Groups that perform comparably when stereotypes are not salient, for example, blacks and whites on academic tasks and women and men on math tests, show significant differences when stereotypes about the group are salient (e.g., blacks are academically inferior to whites, women are worse than men in math). Laboratory studies have delineated the conditions and causal factors at work in these situations; fieldwork has shown the impact of stereotype vulnerability on the academic performance of Black and Latino students (Massey et al., 2003) as well as the successful implementation of interventions to counteract stereotype threat effects (Cohen et al., 2012).

Collective Behavior

Classic theories about crowd behavior, dating from the flawed but influential work of Gustave Le Bon, assume that participation in mass movements leads to a loss of individual identity and loss of rationality and control as well. Although this dehumanizing view might appeal to those in power who want to justify their higher status position, close examination of many protest movements suggests far more rationality and focus than Le Bon allowed. As Reicher and Drury (2011) have argued, participation in group action is a process of social identification, involving transformations in self-conceptualization from individual to group, as well as establishing social relations with others who share the social identity. Thus it may be an individual calculation of needs and potential benefits that motivates the initial involvement in group action, but a likely by-product of involvement is taking on a collective identity that can guide and propel further activity. Collective identities, once established, act as important motivators of involvement in social movements, both for groups attempting to gain recognition in society (e.g., gay rights movements, 'gray panthers' groups representing the concerns of older people) as well as established groups working for redistribution of resources (e.g., labor unions, farmers' movement) (Simon and Klandermans, 2001; Simon, 2011).

Collective identification is thus both cause and consequence of sociopolitical activity aimed at improving the conditions and position of a group within the larger society. Social identities are not the only factor in describing either the onset or the outcomes of this activity. They are, however, inescapably involved in understanding both the antecedents of collective action (e.g., perceived injustice in the treatment of one's group, ideological discontent) and the consequences (e.g., feelings of group efficacy, concrete changes in social policy).

Concluding Comments

Social identities emerge from a process of self-categorization, in which people define themselves in terms their membership in a shared social group or category. A social identity is much more than a categorical label, however, as it includes emotional investment in the category, shared meaning systems, and a potential for action consistent with and motivated by the identity. Consequently, to tap the explanatory power of a social identity, it is necessary to unpack the identity category, looking first at the importance the identity has for any particular person and then further at how other dimensions and meanings are implicated.

Social identities also need to be understood in terms of their potential for change over time (both as discrete categories and in terms of more nuanced and less visible changes in importance and meaning) and their flexibility of use, according to situational demands and opportunity structures. Social identities are important not because they are convenient markers of a particular social position, but rather because they have explanatory value in understanding individual variation in a wide range of thoughts, emotional reactions, and behaviors. They are, in essence, an indispensable link between individual psychological process, social interaction, and social systems.

Social Inequality and Schooling

This article is a revision of the previous edition article by P. Barnhouse Walters, volume 21, pp. 14309–14313, © 2001, Elsevier Ltd.

Abstract

Social inequality in education is universally observed in countries in which children are brought up in unequal families; they enter school with unequal linguistic, cognitive, and cultural assets and attain unequal levels of achievement. Moreover, they make unequal choices, leading to unequal levels of education and social reproduction. However, the latter varies across countries, demonstrating that the way school itself is organized matters. The timing of the selection process and the degree of segregation within the system are especially important, along with the student social mix they generate. As countries implement policies to fight educational inequality, simply expanding education does not prove efficient since it only delays social selection. More qualitative policies then seem necessary, such as limiting early inequalities and focusing on disadvantaged families, which in turn requires broader social policies.

In democratic societies, education-based meritocracy is supposed to prevail. Since it is now considered illegitimate to attain social status by birth, everyone is meant to achieve it through his or her own efforts and merit, displayed by unequal degrees. Education is the main ideological tool used to justify the remaining inequalities in societies where all individuals are considered equal. So it is crucial that equality of opportunities be guaranteed through school competition. The school system is supposed to level the playing field between students so that no inequalities occur based on social background or other ascribed characteristics such as race or gender. The sociology of education shows that such is not the case. Rather, with students from unequal families, the school system proves unable to counter the inequalities visible at the start and, moreover, often allows them to widen. As a result, in recent decades, sociologists have repeatedly demonstrated that schooling plays a pivotal role in the reproduction – and legitimization – of class privilege and social inequality. However, this is not an inevitability; over the last decade, an increasing number of international comparisons have demonstrated that some countries do indeed succeed in reducing this gap through efficient policies.

Social Background and Persistent Educational Inequality

Both sociological researchers and a variety of international organizations, such as the Organisation for Economic Co-operation and Development (OECD), are quite active in producing figures and analysis regarding the social inequality of achievement in the richest countries. Although one is not discussing the world's poorest countries here, one can nevertheless note that in the said countries, it is not primarily achievement at school that makes a difference but rather access to education, given that schooling is far from universal at both the primary and secondary levels. Moreover, a seminal, albeit slightly dated, study by Heyneman and Loxley (1983) suggested that in the poorest countries, evidence of achievement inequality is seen less in the diversity of student population than in the quality of the schools attended. Thus, the issue of social inequality in schooling would be more relevant in the richest countries where (1) school attendance is nearly universal, and (2) the quality of that which both families and schools offer remains more or less heterogeneous from one student (or site) to another.

Large Social Gaps

A variety of indicators and case studies exist regarding social inequalities of achievement (Tesse et al., 2007). They allow us to observe the percentage of the subgroups attaining some level of education or its correlative degree. For example, in France (one of the least egalitarian countries in Europe along with those in central and eastern Europe), the probability of achieving the 'baccalauréat' (the exit exam at the end of upper secondary school) varies from 88% for the most socially privileged students to 49% for students from working-class backgrounds. Moreover, educational inequalities also take on a qualitative form, with some social specialization into different tracks. Today, among those students who reach the final year of upper secondary school, 45% of socially privileged children are in the scientific track compared to about 20% of students from working-class backgrounds. The latter are much more likely to pursue vocational degrees, thus reducing their chances of pursuing tertiary education.

However, probably due to the dissemination of Rawls' conception of justice, it has been judged increasingly relevant to focus not on the highest level of education achieved but rather on the shared basic level of knowledge and skills needed for one to make a good living. Combined with a growing concern for benchmarking that relies on up-to-date country comparisons, this new trend has resulted in the development of comparative studies focusing on knowledge acquired. The most famous study of this kind is the Programme for International Student Assessment (PISA). It is an internationally standardized assessment implemented by the OECD and administered in schools to 15-year-olds, every 3 years from 2000 (see PISA Technical Report and PISA Data Analysis Manual, 2nd edition, 2009). In 2000, 43 countries were included in the first assessment, and in 2009, 62 countries were included in the fourth assessment. That year, between 4500

and 10 000 students in each country were tested on their native language, mathematics, and science. The aim of the exercises was to assess life skills and not just pure conformity to academic knowledge, because the ability to cope with life is the final objective of schooling rather than the mastery of pure academic content.

These surveys provide a solid empirical basis by which to assess social inequality in achievement, at least in terms of the life skills that schooling imparts to students. A gap between students from different social backgrounds is observed in every country, amounting sometimes to the equivalent of two grade levels. However (according to the 2009 data, see OECD, 2010a), this gap is greater in countries such as France, New Zealand, Belgium, Germany, Chile, among others. Conversely, the gap is much smaller in other countries such as Canada, Finland, Italy, Japan, and South Korea.

Moreover, in many countries, first-generation immigrant students are more likely to be poor performers; on average, they are about twice as likely to be found in the lowest quartile of students. In addition, immigrant students tend to be disadvantaged socioeconomically, thus giving them double handicap. Taking into account their socioeconomic status, the specific impact of an immigrant background remains, confirming the fact that some part of those students' difficulties can be attributed to their immigrant status. This is especially the case in Finland, Germany, and Italy, while it matters less in Canada and the United Kingdom.

With regard to gender, in OECD countries (and in a growing number of countries around the world, with the exception of Africa and South Asia), girls today are achieving higher levels of education. Over all OECD countries, 41.5% of women aged 25–34 years receive a tertiary degree, compared to only 32.7% of their male counterparts. In all OECD countries, they also achieve significantly better scores in PISA literacy tests. The male students in every country achieve better scores in mathematics, but the gap is much smaller than in literacy, and in many countries, the difference is insignificant.

Basic Mechanisms

Although PISA surveys focus on inequalities of achievement, research shows that this is not the only process by which social inequality is generated. Actually, two types of mechanisms that result in two types of inequalities should be distinguished: educational performance on the one hand, and educational choices and ambitions on the other. After taking into account class differences in achievement, the latter mechanism results in persistent social inequalities. These mechanisms are labeled as primary and secondary effects. Primary effects result from the accumulation of social differences in cognitive abilities that are visible when a student first starts school. Secondary effects result from choices and strategies observed given the same level of performance, even if they are never completely independent from the student's level of achievement. Social inequalities then become more pronounced whenever making a choice (choice of subject or track) is required. Actually, choices bring about new specific inequalities: whatever their level of achievement, students do implement varying degrees of self-selection; for instance, average students from lower social backgrounds are unlikely to make choices that will place them in the more demanding tracks, while average students from higher social classes will make those choices.

More broadly, at every branching point, students from the lower classes require a higher probability of success than children of higher social origin before deciding to continue schooling. They are not only more risk adverse but also less motivated since they are able to ensure class maintenance (i.e., achieve the same social position as their father) with a lower level of education, as some sociologists maintain. Boudon (1974) asserts that at every branching point, students and their families make choices based on the future they desire, and by comparing anticipated benefits with risks of failure and costs. They develop strategies based on the unequal resources they possess. Parents from advantaged backgrounds want their children to achieve at least their same career level, which in general requires lengthy schooling. At the same time, they tend to be less risk adverse and the cost issue weighs less in their choice. Even when their child is not brilliant, they will choose the most promising tracks despite the risks in terms of success. Conversely, families from less advantaged backgrounds will be more cautious. Thus, even when the students' academic level is the same, strict self-selection based on social background comes into play. In most countries, these secondary effects play a significant role in social inequality; for example, they account for about 25% of the social selection at the A-levels in Great Britain (Breen and Jonsson, 2005).

The Role of Family

Given that children are raised in unequal environments and in families that possess unequal cultural and economic resources, it is not very surprising to observe such social inequality in schooling. One expects that parents will strive to transfer their knowledge, tastes, and assets to their children so as to secure their own future as well as to reproduce their social status. The French sociologist Bourdieu (with Passeron, 1990) designed a theory that focused on the concept of cultural capital. He maintained that students have varying degrees of familiarity with the dominant culture that school is supposed to impart because they inherit unequal cultural capital from their parents. Students possess specific assets such as cultural codes, modes of conduct, use of language, and also stronger motivations; this is why certain students – the 'inheritors' – perform better at school. However, the British sociologist Sullivan (2000), after achieving a concrete operationalization of the concept of cultural capital, showed that the cultural capital acquired through participation in formal cultural activities (i.e., the theater, art galleries, and concerts) does not significantly alter the development of knowledge and skills that help students to better succeed at school. Students' reading and television habits (when children watch relatively sophisticated programs) prove more important, as they foster intellectual resources that are advantageous at school (assessed early in lower secondary school).

Moreover, the contents of education itself matter. Sociologists such as De Graaf et al. (2000) have suggested that social inequalities may be wider in France and Eastern European countries because they give more importance to the humanities (or highbrow culture), thus giving an advantage

to those students whose parents are well educated and possess this kind of capital. However, this is less the case in countries with curricula geared more toward everyday life skills.

However, according to Bourdieu and Passeron's theory, the education system is not a neutral field divorced from society as a whole. Rather, the culture and standards within the education system reflect society and, in doing so, schools systematically benefit those who have already acquired cultural capital through their family and other social networks. Higher class children easily fit into school culture. Moreover, because the education system is portrayed and widely perceived as being open to all on the basis of talent, many working-class children come to see themselves as intellectually inferior; they accept that they, rather than the system itself, are to blame for their failure. In this way, the education system plays a key role in the cultural reproduction of social inequalities; educational credentials help to reproduce and legitimize social inequalities, as higher class individuals are seen as deserving of their place in the social structure.

Because they were focused on the social function of schooling, these sociologists did neglect the possibility that social inequalities in achievement may also result from true cognitive weaknesses that exist when students enter school. A number of studies (see, for instance, Mercy and Steelman, 1982) show that as early as ages 2 and 3 years, children are already on unequal footing in terms of mastering of language, time, and space, which in turn plays a role in them learning how to read, etc. In the 1970s, the British sociologist Bernstein (1975) while investigating the way in which education reproduces class inequalities produced an analysis of linguistic skills. He argued that children from varying backgrounds develop different language codes (or forms of speech) during their early lives, which in turn affect their subsequent school experiences. His interest was in the systematic differences between the ways in which language is used. He distinguished between a restricted code (a code containing many unstated assumptions that speakers expect others to know, thus making it difficult for nonmembers of the speaker's group to understand) and an elaborated code (a style of speaking in which the meanings of words can be individualized to suit the demands of particular situations). Bernstein proposed that children who have acquired elaborated codes of speech are more able to deal with the demands of formal academic education and easily fit into the school environment. Thus, language is a vehicle of social inequalities between students.

Psychologists show that, across the board, cognitive skills and, more broadly intelligence, develop through social interactions, and that parental practices in a child's daily life do affect his or her cognitive development. Just as disparities in living conditions give rise to unequal health conditions, it has been demonstrated that certain forms of socialization do indeed cause some advantages or disadvantages in children. In particular, adaptable and flexible educational practices (children learn both rules and exceptions that may be justified), and encouraging children to freely explore their surroundings and consider the results of their own actions all have a positive effects on cognitive development. In addition, as parents teach their children that they are personally responsible for what happens to them, they foster self-confidence. The most privileged parents implement what the American sociologist Lareau (2011) calls a 'concerted cultivation,' thus maximizing their children's opportunities to learn and develop, while the least privileged are less active, letting a more 'natural growth' occur.

Those attitudes and practices are linked to school success later on, given that the most favorable practices are more widespread among educated or sufficiently well-off families. That is an important vehicle of social inequality, especially given that school is unsuccessful in compensating for early inequalities and in leveling the playing field. Moreover, as evoked, social differences in risk aversion and educational choices do widen the social gap that results from parents' educational practices. However, with the growing prevalence in sociology of a less deterministic conception of social phenomena and a more assertive conception of the actor, more attention has been given to the context in which these social inequalities are generated.

School Matters

The school, the teachers and their pedagogical practices, the way students are grouped in classes, and, more broadly, the organization of the education system itself, all these contextual dimensions create the framework in which students behave. As Coleman et al. (1966) showed a half century ago, family factors are generally more important predictors of academic success than school factors; however, that is true mainly in countries in which a minimum level of quality of these school factors is warranted. Moreover, school factors are things that are amenable to social policy interventions in ways that family factors are not.

The Story Told by International Comparisons

While the relationships between students' socioeconomic background and achievement prove constant across countries, they also vary in extent. That is, of course, related to the level of socioeconomic inequalities prevailing within the countries themselves. Nordic countries have both low income inequality and equal performances, whereas many English-speaking countries have both large income inequality and large performance inequality. However, the correlation does not hold invariably. PISA data show (in a rather constant way since the 2000 study) that countries where socioeconomic inequality between families is similar may have a varying degree of social disparities in achievement across students. Both New Zealand and Japan have rather wide gaps in income inequality, but educational inequality is much greater in the former that in the latter. The same is true for Belgium and Finland, where income inequality is rather moderate but, once again, educational inequality is much greater in the former than in the latter. In some countries like Australia, both strong income inequality and relatively weak educational inequality exist; conversely, in other countries like Germany, there exists both a great educational inequality and a rather moderate income inequality.

International comparisons are here very heuristic (Janmaat et al., 2013; see also OECD, 2005, 2010a,b). They suggest that some educational systems are indeed capable of compensating for social inequalities, with students proving less unequal

academically than the families they belong to, while others seem to augment the impact of social origin on student performance. Before investigating which characteristics of the education systems may explain this variation, it is to be stressed that, contrary to the widespread common view, there is no trade-off between students' average level and the amount of social inequalities, since the mean performance level is high in the most equal countries (Finland, Japan, and South Korea), even though it is also quite high in some unequal countries (Canada and New Zealand).

Comparisons (such as those led by Green and others on the 2006 data set; see Green et al., 2006) show that all the more equal countries (East Asian and Nordic countries) have comprehensive systems (at the lower secondary level), while among the unequal group (Anglo-Saxon and German countries), 5 of the 10 systems are selective at the secondary level, and four are highly marketized comprehensive systems. More precisely, what the more equal countries have in common, and what is absent in the less equal countries, are structures and processes typically associated with radical versions of comprehensive education: nonselective schools, mixed-ability classes, late subject specialization and measures to equalize resources between schools. All these features contribute to lowering educational inequality.

Another factor that may explain these differences in social inequality is the school intake mix. Measured in terms of average parent job level, wealth, and cultural capital, it has a major impact on the performance of individual students internationally. PISA data show that in English-speaking countries, because the social mix is much more diverse (it varies greatly from one school to another), the school intake mix has a much larger impact on the differences in outcomes than elsewhere. For all OECD countries taken together, school social mix explains 34% of the variance in average outcomes in literacy between schools, whereas in English-speaking countries, its impact is much higher; it explains 64% of the between-school variance in Australia, and 61% in the United States and the United Kingdom. Conversely, in Japan and South Korea, the impact of school status on differences in school outcomes is much lower, explaining 11 and 17% of between-school variance, respectively. Intake effects are also moderately low in Scandinavian countries. Thus, just how much the school attended matters varies across the countries under comparison, and it appears that greater social segregation in school intakes increases educational inequality, whereas increasing the heterogeneity of intakes and narrowing the gaps between schools reduces it. Nordic and East Asian countries appear to have considerably less segregation in school intakes than most of the English-speaking and German-speaking countries and the effect of intake differences on inequalities between schools is much lower.

All in all, while it has been shown that international difference in student performance cannot be attributed to resource differences (Wössman, 2003), the way education systems are organized certainly matters.

The Impact of Organizational Characteristics

Educational research illuminates the ways in which some characteristics of education systems (e.g., the age at first selection, or branching point, the length of the common curriculum, and the social segregation of schools, strongly correlated with the existence of distinct tracks) magnify social inequalities. One reason why is that, in accordance with Boudon's theory, systems with several strategic choices give more latitude to inequalities resulting from the different trade-offs between the costs, risks, and expected benefits that unequal families make for their children.

However, the fact that the systems are differentiated may have an impact in quite a different way, thus putting academic learning at stake. In countries where early selection prevails, children from less advantaged groups tend to attend the weakest tracks and schools. In these settings, the disciplinary climate and teaching conditions are less favorable and the curriculum is less ambitious; fewer resources may also be allocated to these schools. As a result, the gap between levels of academic achievement within such systems widens just as it does between different social groups.

Another factor concerns the impact of the social mix, with the consequence that social inequalities will be larger in countries where the social mix largely differs from one school to another. This is because the composition of the student body itself contributes to creating an environment of inequality. Classmates are resources for one another (the so-called peer effect), meaning that student achievement depends positively on the average achievement in the reference group (the probability that an individual behaves in a certain way increases with the presence of this behavior in the group).

The social mix also impacts the climate of the class and influences which teaching practices are possible. For example, much research shows that students from working-class backgrounds attending a mixed-intake school progress better. Because those students have contact with students who are more adjusted to school norms and have greater cultural resources, they draw benefit from this and are less likely to develop antischool attitudes. They also develop more ambitious educational aspirations. The issue of peer effects is relevant to policy making because it can serve as a basis for relocating students to different schools, with the argument that weak students would benefit if they were in a class with high-performing students. It could even enhance the global efficiency of the system whenever peer effects are higher for low-skilled students (generally, peer effects prove asymmetric, as they favor weaker students).

Teachers also adapt their practices to the student body. They are more demanding in the best tracks and schools, and their expectations tend to foster inequalities present from the outset. In systems that differentiate between students, what they can expect is strictly limited. Actually, some PISA data show (see the analysis of PISA, 2000 and 2003 data sets led by Duru-Bellat et al., 2008) that in countries where school systems are the most differentiated, relatively few students say that their teachers show interest in every student's learning. Similarly, relatively few students say that their teachers help them with learning in most lessons. More broadly, the faith in the capability of every student is less widespread in differentiated systems. Conversely, in an egalitarian country such as Japan, there is a widespread belief in the ability to learn of every pupil.

It should also be noted that while the above-mentioned processes are currently considered as demonstrated, some

debates exist regarding the impact of other characteristics of education systems, like the degree of centralization versus decentralization, the role of competition between schools and of school choice, and the weight of school autonomy versus an important role for the State. However, what is mainly under discussion is the impact of the marketized system (with choice, competition, and autonomy) on students' mean performance. In any case, this impact, be it positive or negative, is never dramatic; however, the fact that it results in increased inequality seems more consensual (Van de Werfhorst and Mijs, 2010).

Last but not least, one may stress that the results of cross-sectional studies such as PISA, and the different policy measures that can be drawn from them can be significantly enhanced through the implementation of a longitudinal component; that is the only way to establish causal links between policies and outcomes and some countries such as Canada or Germany have yet engaged in this kind of study (see OECD, 2010b; Blossfeld et al., 2009).

Democratizing Policies

Around the world, especially in the most advanced economies, education has developed over the most recent decades, with several aims. One is to position the country in a global competition that requires increasingly higher skills, toward the end goal of achieving a knowledge society. Another is to fight against social inequality, which is both wasteful and unbearable in an education-based meritocracy. Thus, the democratization of education has been on the political agendas of most countries (Duru-Bellat, 2004).

The most obvious way to achieve this dual aim seemed to be to simply expand access to education. Obviously, when a whole generation has access to upper secondary school, some social inequality is erased. Thus, lengthening schooling careers may be considered an efficient way to enlarge access to education and, thus, democratize upper secondary and tertiary education. Actually, the expansion of education has indeed resulted in some democratization, especially at the highest level of education reached (although the increased wealth of most countries may have played a part; Breen et al., 2009). But research shows that most often the emergence of social inequalities is only postponed. That is because in order for the most advantaged families to stay ahead, they will often strive to keep their children in school longer. That generates a global trend, often labeled credential inflation, where all students must study longer and longer in order to get the same returns.

This evolution has two broad and unexpected consequences. First, social educational inequality does not really decrease as long as students remain unequally endowed with cultural resources and previous levels of achievement, but rather only shifts it to an upper level so that, ultimately, diplomas remain the gatekeepers of social (im)mobility and inequality is 'maximally maintained,' as Raftery and Hout (1993) suggested two decades ago. As Walters (2000) suggested, growth operates here both as a safety valve and as a counter reform, not allowing things to change. Second, as in economic inflation, this credential fosters a depreciation of the economic worth of the degrees themselves (Büchel, 2003).

Actually, according to Kerckoff's analysis (1995), the function of schooling is twofold; every society channels its members into the social positions through two broad families of institutional arrangements, thereby reproducing the process by which each generation becomes distributed into the unequal positions of society. In the first stage – the institutional arrangement devoted to achieving the socializing function – children are channeled into educational tracks, which results both in social inequalities in achievement and in specific and segregated socialization and training. In the second stage, devoted to achieving the allocation function, students are channeled into jobs based on their credentials; however, this process also relies on other parameters that vary across countries. Despite this illuminating distinction (socialization and allocation), most sociological theories analyzing social reproduction have focused on the crucial socialization function that schools play in this process (notably Bourdieu and Passeron, 1990). The implicit hypothesis is then that getting a university degree is the key to getting a job, as if the allocation process was unable to add any specific additional inequality. Thus, the education level achieved is seen as the main vehicle of social reproduction, through the inequalities of achievement generated within schools. Only recently have some sociologists dared to ask whether it is really so obvious, while fighting social inequalities of achievement is a legitimate aim in and of itself (if education is considered a good and not just a positional asset), it will not dramatically reduce social reproduction.

Here, one may recall Boudon's prediction (1974) that educational inequalities may well decline without causing a corresponding change in the structure of social inequalities. That is because the process of social reproduction itself appears to be intimately embedded in the structural framework of the job market and its evolution. Actually, individuals, whatever their personal attributes, insert themselves into a society whose places are predefined, and even if education is a relatively effective way of accessing the best positions, the definition of these places themselves (and more broadly how society is stratified and unequal) does not fundamentally arise from this action. Similarly, the educational system has no power over the effective market value of the degrees it issues, which itself results from the structural distribution of jobs and the peculiar relationships prevailing between degrees and qualifications. If, as has been observed in most modern countries over recent decades, the expansion of the social structure at its highest end has been slower than the rate at which graduates who might fill this level are produced, an adjustment will be made in the form of credential devaluation.

This crucial role of discrepancies between education (its structures and its evolution) and social reproduction would have one shift the focus to the relationship between education and jobs; what takes place within education would have less influence than the interaction between what the education system 'produces' – the credentials – and social stratification itself. Today, with the rise of youth unemployment, it is all the more valuable to investigate the relationships between degrees and employment as a specific process in the global reproduction process.

Because the concern for youth employment has moved up on the political agenda, education policies and the goal of democratizing education as a whole may see some changes. On the one hand, mandating that all students have the same basic knowledge is the best way to ensure that they find jobs later on. Thus, adopting policies aimed at canceling early tracking and developing common core schooling has been encouraged by the OECD, in conformity with the comprehensive ideal. However, a recent study (Bol and van de Werfhorst, 2013) has shown on a comparative basis that educational systems with a high level of early tracking accompanied by a vocational orientation do improve student allocation in the labor market. As this kind of system is also known to expand educational inequality, there may be a trade-off for systems and policy makers in economic efficiency (through youth employment) and equity of education.

A less ambivalent policy, still more assertively promoted by the OECD, is to give priority to tackling the achievement gap from the very start through early childhood provisions and preschool education. The effects of such programs include better educational achievement as well as, much later on, better employment rates and earnings, crime prevention, satisfying family relationships, and improved health. Therefore, they are often seen as the best methods for producing the highest returns, that is, creating the basis not only for better success at school, but also, more broadly, for better life opportunities. However, some argue that the results of these programs are often uncertain and that it would be more cost-effective to implement actions devoted to parents (e.g., like the parent education programs implemented in Belgium) in order to foster among parents specific forms of educational expertise such as linguistic interactions, learning incentives, reading books, and connecting to schools and teachers.

Of course, one could also argue that it would be still more effective to reduce poverty among the targeted children's families. It is widely recognized that education cannot be the only vehicle used to achieve equity and social cohesion. Education is nested in society as a whole and it seems impossible to achieve true equality of opportunity in an unfair society. Actually, the only countries in which some significant democratization has been observed (Northern European countries) are those that have implemented larger social welfare policies.

Social Inequality in Cultural Consumption Patterns

Koen van Eijck, Erasmus University Rotterdam, Rotterdam, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social inequality in cultural lifestyles can be understood using cultural capital theory or status theory. Empirical studies cannot easily produce results that allow for a proper comparison of the merits of these theories. In addition, the central role of habitus in both theories is problematic from a theoretical perspective, as relations between habitus and observed behavior are not straightforward and much of cultural behavior is affected, if not shaped, by variable social contexts.

Introduction

Cultural consumption patterns have solid social roots. They are affected by parental schooling levels and family socialization, level of education, occupational status, and income (Chan, 2010; Mohr and DiMaggio, 1995). All of these determinants are somehow related to class and status, thus causing social inequality in cultural consumption.

The central aim of this contribution is to assess the merits of the main theoretical explanations for this social inequality in cultural consumption by evaluating the existing empirical evidence. The most prominent theoretical accounts, i.e., cultural capital theory and status theory, will be addressed. Difficulties with attempts to empirically settle which one of these theories is more valid will be addressed. In addition, special attention will be paid to the habitus as the linking pin between socioeconomic background and cultural lifestyles. Finally, possible directions for future research are suggested.

Cultural Inequality: Theoretical Accounts

Cultural inequality can be theorized to follow from differences in skills or resources. It takes resources, or capital (cultural, economic, and social) to develop and implement a certain lifestyle. Unequal command of these resources leads to different lifestyles. This ties in with a second common theoretical account, which sees lifestyles as expressing social honor or prestige by demonstrating access to certain, more or less scarce, resources. Such prestige may not only be a mere by-product of a lifestyle, but it may also be a reward that is consciously sought after by engaging in certain esteemed activities.

Knowledge and Resources

According to Bourdieu (1984), cultural lifestyles depend primarily on cultural capital. This cultural capital is acquired during (early) socialization and inculcated in the habitus, which structures subsequent cultural practices. This entails a process that Bourdieu called cultural reproduction, where parents rich in cultural capital transmit this capital to their children, who simultaneously invest and expand it in their educational career and emerge out of this process endowed with a large amount of cultural capital of their own. The cultural skills thus embodied engender an aesthetic disposition that encourages a taste for highbrow culture.

Behind this reasoning lies the assumption that highbrow culture is more complex than popular culture. Thus, in his *information-processing theory*, Ganzeboom (1982) argued that the ability to process complex cultural information is a requirement for highbrow cultural consumption. This argument was based on the work of Gary Becker (1964) on human capital, Bourdieu's notion of cultural capital (Bourdieu and Passeron, 1977), and more psychological ideas from Berlyne (1974). The latter rest upon assumptions regarding the complexity of cultural stimuli, which are hard to assess empirically. However, it does make intuitive sense to assume that the joy derived from cultural consumption depends on people's ability to interpret them. The most pleasurable experiences occur whenever people's skills at deciphering a cultural stimulus match the challenge, or complexity, posed by this stimulus. It thus follows that, in order to enjoy complex culture, one needs the cognitive resources, or skills, to deal with this complexity. These skills depend on intelligence, experience, or creative talent, which are partly reflected in schooling levels, but also enhanced by cultural socialization and acquaintance with the world of culture. This is cultural capital theory's explanation for lifestyle differentiation in a nutshell: people and cultural activities can be matched to one another because differential socialization practices lead to different information processing skills and cultural activities differ in the skills they require.

Status and Social Prestige

People's cultural lifestyles tell us something about their social position. Society at large confers a certain amount of honor to members of specific social classes. Belonging to a certain class can be signaled by displaying the appropriate lifestyle. It is exactly because they indicate the possession of certain skills and resources that cultural lifestyles have a communicative function allowing them to convey a certain status.

At the close of the nineteenth century, Veblen (1953[1899]) argued that lifestyles mainly reflected economic differences. He coined the term *conspicuous consumption* to indicate that the overt possession of expensive consumer goods functioned as an effective mode of status display. Ten years after Veblen's mocking account of the upper classes of his day, Weber (1968

[1909]) argued that economic differences were not the only source of social inequality. He opposed to a one-dimensional view of stratification with his distinction between class and status. Class structure, he argued, was formed by economic relations rooted in labor markets. The status order, on the other hand, was structured by relations of social superiority and inferiority among individuals on the basis of the social honor attributed to them. This honor was conferred on the basis of social (class) position, but descent from founding families or birth into the nobility were also sources of such honor.

Bourdieu (1984) treats status as the symbolic aspect of class structure, but he too argues that class positions are not defined by economic resources alone. Rather than assuming objective class boundaries based on economic structures, Bourdieu focuses on "the structured formation or self-production of class collectivities through struggles that simultaneously involve relationships between and within classes and determine the actual demarcation of their frontiers. Bourdieu replaces the concept of class structure with that of social space, understood as the multidimensional distribution of socially effective forms of power (or capital, be it economic, cultural or social) underlying social positions" (Wacquant, 1991: p. 52). Most notably, Bourdieu introduced cultural capital as a relevant noneconomic source of social inequality and as a tool for social reproduction in a society where the direct intergenerational transmission of economic resources became incompatible with meritocratic ideals (DiMaggio, 1979).

Thus, cultural capital can be seen as both a bundle of knowledge and skills and a status symbol. The latter aspect of lifestyles is represented in Ganzeboom's *status-seeking theory*. Status theory as presented by Ganzeboom is rooted in conflict sociology, taking its inspiration mainly from Weber (1946 [1922]), Veblen (1953[1899]), Collins (1979), and, again, Bourdieu and Passeron (1977). Here, lifestyles are primarily considered as criteria for demarcating and identifying class groupings. Cultural lifestyles are then seen as primarily reflecting the status-rendering characteristics of the behaviors and taste patterns involved. Simultaneously reflecting the honorable investments of time, money, and knowledge, highbrow culture participation has been an excellent way to demonstrate social worth. As long as others believe that this type of culture requires special skills and sensibilities, it also helps legitimate the high-end social positions of the highbrow audience by demonstrating their exquisiteness. Culture can thus be used to exclude people with 'bad' taste and include those who are socially and culturally similar to oneself.

Empirical Tests of the Theories

Above, it has been explained that cultural lifestyles can be seen as either reflections of knowledge, skills, and attitudes, or as indicators of status group membership. In his discussion on the concept of cultural capital, Lizardo also addresses the general distinction between skills vs status seeking. On the one hand, he argues that cultural capital can indeed be defined as "an aptitude or a generalized, transposable (across contexts) skill acquired in the combined realms of the upper-middle class family and the school system" (Lizardo, 2010: p. 310). In addition, he distinguishes what he calls the boundaries point of view, where cultural capital is defined as the institutionalized repertoire of high status signals useful for purposes of marking and drawing symbolic boundaries in a given social context. In the boundary perspective, the link with specific cognitive requirements as to the content of cultural capital is largely absent, since "what counts as cultural capital are those symbolic resources that are actively mobilized by members of groups or class fractions to establish their difference from other groups and thus to devalue the cultural resources and symbolic practices of outsiders" (Lizardo, 2010: p. 310). Bourdieu similarly talked about a 'cultural arbitrary,' indicating that it does not matter much which exact cultural taste the upper classes display; it is in large part the fact that *they* have this taste that makes it a form of cultural, or symbolic, capital. Although, at a more general level, lifestyles reflecting the ability to spend money or to deal with complexity will be more prestigious than lifestyles that require no such investments (Prieur et al., 2008), the symbolic value of cultural lifestyles is defined as a function of the social prestige of its possessors as much as in terms of properties of specific cultural items or activities such as complexity or rarity. This conflation of cultural capital as skills and cultural capital as a status marker makes it hard to empirically determine which theoretical account of social inequality in cultural lifestyles is more valid.

Mapping Social Background Effects

Cultural lifestyles symbolize status positions by pointing at certain skills, attitudes, knowledge, taste, or other resources. A resource that has consistently been found to be a very strong determinant of cultural lifestyles is educational attainment (Kraaykamp and NieuwBeerta, 2000; Van Eijck and Bargeman, 2004). For Ganzeboom (1982), effects of educational attainment substantiate the impact of knowledge. In addition to education, however, occupation and income also show up as recurring sources of lifestyle differentiation. For a proper understanding of the relation between lifestyle and social positions, these prime sources of stratification will be compared and the findings will be linked back to the work of Veblen, Weber, Bourdieu, and Ganzeboom.

According to Lizardo (2008: p. 5), we are witnessing a "systematic transition in the cultural stratification system of the Euro-American West starting in Renaissance Europe from a regime premised primarily on the differential ability to *own* objectified cultural products – with a contemporaneous 'relative democracy' of the ability to appropriate cultural works symbolically – to a cultural stratification regime which devalues the *sole* deployment of the direct appropriation strategy and which emphasizes symbolic appropriation." There can be no doubt that this implies a shift from economic to cultural characteristics as the main determinants of lifestyles. Income should therefore be a less relevant background characteristic than education or other background features related more directly to cultural capital.

Although the literature on cultural lifestyles is very much scattered, a relatively clear picture as to the causes of lifestyle differentiation emerges. Indeed, income seems to be mostly inconsequential when mere preferences or low-profile participation (reading, listening to music) are concerned rather than relatively expensive outdoor practices (Berghman and Van

Eijck, 2009; Chan and Goldthorpe, 2007a; DiMaggio and Useem, 1978; Van Eijck, 1999). Veblen's notions of conspicuous consumption and conspicuous leisure based on income differentiation are clearly not very helpful for understanding lifestyle differentiation today. Income is of relatively little use if we want to understand taste differences. When actual behavior outside one's own home is the dependent variable, income effects are somewhat more common (Bihagen and Katz-Gerro, 2000; Kraaykamp et al., 2007; Van Berkel and De Graaf, 1995). Income seems to only affect activity per sé, distinguishing between, e.g., those who do not attend visual art institutions at all vs those who do so (Chan and Goldthorpe, 2007b). It hardly differentiates between one expressed preference or type of participation and another. Thus, it seems valid to assume that income is a prerequisite for consumption rather than a clear cultural tastemaker, as Ganzeboom (1982) argued.

Occupational class or status is often found to be more important than income (Alderson et al., 2007; Chan and Goldthorpe, 2005; Kraaykamp et al., 2007). Class or status positions clearly represent more than a person's place in a straightforward economic hierarchy. Given the prevalence of status effects over class effects in most of the analyses reported in Chan (2010; see also the contributions to the special issue of *Poetics* (35: 2–3) entitled 'Social status and cultural consumption in seven countries'), social status still seems to play an important role, also after income is controlled for. The importance of status over occupation lends support to a conceptualization of lifestyles as expressions of social group membership, or socio-cultural boundaries, rather than of specific cultural or economic resources.

Yet the most important determinant of cultural lifestyles is education (Chan, 2010). It is not exactly sure what this means, as education seems to enhance all sorts of activities, not just the more complicated or elitist ones, without guaranteeing a very intellectual mode of appropriation. Nevertheless, cultural capital strongly structures lifestyles, as Bourdieu posited. Even if relations are less deterministic than he suggested, the idea of a certain homology of social and cultural positions still has merit. This is further confirmed by the analyses of specific job characteristics. Where income merely affects some forms of participation per sé, education and, to a lesser extent, occupational status additionally differentiate between distinct taste patterns. Finally, much of the analyses referred to here demonstrates that education, income, and occupational status have unequal yet cumulative effects. Social stratification is more than income, occupation, or education: it is a combination of each of these, where education is the element that is most consequential for lifestyle formation, followed by occupation and, lastly, income. This order of importance is in line with the embodied cultural capital regime sketched by Lizardo (2008). The link between taste and education as a cultural structuring principle of social space is and remains very strong.

Cognitive vs Status Indicators

It is difficult to draw strong conclusions regarding the rivaling accounts of cultural lifestyle differentiation from these findings. Status attainment theory and information processing theory often come up with similar predictions, such as positive effects of cultural family socialization or educational attainment on highbrow cultural participation. Clever, detailed hypotheses are needed in order to generate test results that actually differentiate between the two perspectives. What is especially needed is a way to disentangle the different potential effects of education, as schooling has both cognitive (resource) and status (boundary) consequences. This requires detailed measures of cultural capital that allow scholars to distinguish between (effects of) cultural knowledge and (effects of) cultural status. This has been attempted in studies on educational attainment, where distinctions were made between effects of parental reading and parental beaux arts participation (De Graaf, 1986; De Graaf et al., 2000). De Graaf interpreted effects of parental reading as representing an impact of educational resources, or skills, whereas the absence of parental beaux arts participation effects was argued to disprove the relevance of highbrow status culture involvement. Sullivan (2001) provides a more direct measure of cultural capital as information (processing) and finds that the effects of pupil's reading on their scholastic achievement are fully mediated by their vocabulary and cultural knowledge. She concludes that "the reason for the effect of cultural participation on academic attainment is that cultural participation is associated with intellectual resources which help pupils at school" (Sullivan, 2001: p. 910). Cultural knowledge also turned out to be more relevant than beaux arts participation later on in the educational career (i.e., admission to Oxford University: see Zimdars et al., 2009). In a sense, such tests offer what Ganzeboom (1982: p. 188) suggested as a first test, i.e., assessing whether the highest correlations are found between activities that demand equal types of skill and knowledge, or between activities that demand the same kind of formal attendance. If education is more closely correlated with (parental) linguistic skills and knowledge than with (their) beaux arts participation, information theory seems to offer the best explanation for the intergenerational reproduction of educational opportunities.

But why does education, in its turn, enhance cultural participation? Is this a matter of having received relevant instructions or pertinent information too? Nagel and Ganzeboom (2002) assessed the impact of taking arts education classes on participation in legitimate culture. These effects were found to be small and in fact attributable to self-selection (their longitudinal design showed these 'effects' to be present already at age 14, before actual enrollment). Similarly, differences in cultural participation between educational categories were already partly present before the educational career was finished due to differential family socialization (Nagel, 2010). These results should not be too surprising, as there is little emphasis on highbrow culture in school curricula in countries such as Britain, the United States, or the Netherlands (De Graaf et al., 2000; Sullivan, 2001). But here too, elaborate path models would be required to fully disentangle the effects of information processing and status attainment using very specific cultural capital indicators.

Another possible way of disentangling status- and information processing effects would be to focus on instances of status inconsistency or social mobility. Whenever people have schooling levels that do not match their socioeconomic status, there is more room to assess effects of status indicators such as occupational prestige or income and information processing

indicators such as education separately. In such instances, people have different ranks in relevant status dimensions. For example, occupational status only affects cultural taste if one's occupation is high relative to one's schooling level (Ganzeboom, 1982). In that case, we are also most likely to find extra high levels of material consumption (De Graaf, 1991). Similarly, if marriage partners have different status characteristics, De Graaf observed status-maximization effects indicating that the partner with the highest education most strongly determined the cultural participation of the spouses. Such effects are to be interpreted most likely in terms of status seeking rather than information processing.

Finally, looking at changes in cultural lifestyles during the life course might be informative. What happens when people change or lose their job or their spouse? Under such circumstances, their status and social networks may change while their cultural capital does not. Ganzeboom also interprets the strong and lasting effects of early cultural socialization as evidence in favor of information theory, but it may also be argued that, e.g., getting acquainted with highbrow art in the early family context does not only enhance cultural knowledge but a sense of status as well. What he does rightly stress throughout, however, is the need for multivariate analyses because of the intricate relations between family socialization, education, cultural knowledge, and social status. Both theories have their own merits and help explain part of the differences in cultural lifestyles. The main problem is that the social indicators that are most available to sociologists, such as schooling level or occupational status, also combine elements of status and information which makes it difficult to interpret schooling effects as support for information theory or effects of occupational status as support for status-seeking theory. Above all, we seem to need more detailed measures of these background indicators for incorporation into multivariate models.

Criticisms and Controversies

The question whether cultural lifestyles are determined by either cultural resources or status considerations seems hard to resolve empirically. Apart from difficulty in finding appropriate quantitative measures, it can be argued that this dichotomy is conceptually problematic as well. The theories assume that either a cultural disposition or a status position can be largely held responsible for cultural lifestyles. As such, they both assume that a certain, typically class-specific, habitus is translated more or less consistently into observable cultural behavior. This central assumption is problematic for at least three reasons, as will be outlined below.

Deducing the Habitus from Observed Behavior

Since habitus cannot be observed directly, many studies observe cultural behavior and infer from these observations which habitus must be underlying this behavior. For example, if a person attends a ballet performance, it is assumed that this behavior indicates the presence of an aesthetic disposition, or a habitus geared toward highbrow art forms. Several studies have convincingly refuted the validity of this assumption.

In 1993, Halle published his study of the art people put in their homes. He found that members of the upper middle classes were much more likely to display abstract art in their homes while working class families preferred religious iconography. This observation would suggest the existence of distinct class habitus causing these differences in home stylization. However, Halle found that the upper classes wanted their abstract art to be decorative and to symbolize aspects of their everyday lives. Similarly, the reasons why the upper classes display primitive art show a remarkable resemblance to why the working classes put up religious art as both groups attribute symbolic meanings to these works that were related to their own social world. Thus, Halle concluded, distinct behaviors may well imply quite similar habitus.

Although Holt (1997a) does not agree with Halle that his findings imply the invalidity of Bourdieu's theory of taste, elsewhere he does provide evidence of the complexity of the relation between habitus and cultural behavior by criticizing the idea that lifestyles are shaped by universal traits or values and the notion that meanings of cultural behavior can be inferred from intrinsic qualities of the activities engaged in (Holt, 1997b). Thus, he demonstrated that people who share a love of antique furniture may have very distinct reasons for doing so, ranging from enjoying the bargaining involved to true connoisseurship to bricoleur refurbishing. In a similar vein, Bennett et al. (2009) have shown that highbrow cultural behavior can imply very different underlying motivations or dispositions. For example, opera attendance in the United Kingdom is more often part of a work-related social event than an expression of a personal predilection for the genre. And listening to classical music is often described as 'soothing,' 'relaxing,' or something that 'gets the women going' (Bennett et al., 2009: p. 83), implying the application of more or less functional criteria pertaining to mood management (DeNora, 2000) rather than employing aesthetic categories. Again, similar activities or preferences are linked to highly divergent habitus while seemingly distinct preferences do not necessarily imply equally distinct dispositions. In short, habitus cannot be deduced directly from the cultural preferences and practices we observe. This is especially problematic since habitus is often a black box that is assumed or derived from observing something else (either socioeconomic background or cultural behavior), to which it does not relate in a straightforward manner.

Predicting Observed Behavior from the Habitus

Moving the other way around, from the habitus or cultural dispositions to observable cultural taste or behavior, is problematic as well. Lahire (2003) criticizes the theoretical use of dispositions as if they were transferable, always active, and neatly aligned rather than context dependent, regularly on standby mode, and internally incoherent. The activation of people's multiple dispositions depends on opportunity structures that may or may not allow people to actually act in accordance with their dispositions. But a lack of correspondence between what people believe (dispositions) and what they do (action) is not just due to practical barriers keeping people from pursuing their inclinations. According to Lahire (2003), we must acknowledge a more fundamental difference between dispositions to act and dispositions to believe. The latter, beliefs, are inculcated by socialization in the family and a range of institutions, such as school or media of all sorts.

These beliefs are, however, not necessarily confirmed by everyday experiences and therefore differ in their strength. They may be unrealistic in themselves (I must be rich/beautiful/happy/clever), but they may also lack rapport with practices because the latter may be hard to control (eating habits, addictions, and neuroses). That is why Lahire differentiates between dispositions to act and dispositions to believe. Yaish and Katz-Gerro (2012) similarly demonstrate that cultural tastes are more strongly determined by socialization than cultural participation, whereas participation is more determined by economic resources and less by cultural resources than taste. These findings, too, demonstrate that different processes are at work in shaping dispositions to believe (taste) and dispositions to act (participation).

Dispositions to act and dispositions to believe are affected not only by partly different resources, but also by a multitude of social agents and institutions. Therefore, "we cannot act as if a single system of cultural beliefs existed at the same moment in every part of the social world, as if all the social groups tended to fall into line with the legitimate consumption of the most 'cultivated' of the members of the intellectual fractions of the dominant class" (Lahire, 2008: p. 172). As a consequence, cultural lifestyles are hardly ever consistent in terms of cultural legitimacy. Instead, Lahire argues that contemporary cultural lifestyles are dissonant, and that individuals are typical and marginal at the same time as their daily lives propel them to shift from one cultural register to another. Rather than being straightforward embodiments of the taste of their social class, individuals move about in a complex world full of social obligations, routines, secret pleasures, family duties, professional networks, or inaccessible events. When the social world gets more heterogeneous or fragmented, the incorporation of this social world becomes less likely to result in a robust, univocal habitus that functions as a reliable guideline across the different contexts in which people find themselves.

Context and the Flexible Habitus

More than half a century ago, Goffman (1959) illustrated how frequently and often automatically people switch social roles depending on the situation or company they are in. This may occur unconsciously, as part of everyday routines, but people also intentionally manipulate the impression they have on others by adapting their self-presentation to the circumstances at hand. This flexibility not only makes social interaction run more smoothly; it also implies that different schemes of action are called upon in different contexts, thus corroborating the above implication that habitus does not always drive action in a straightforward manner. Thus, Lahire (2008: pp. 181–182) claims that "some individuals sometimes spend more time doing things or consuming cultural products for which they do not have a particularly pronounced 'personal taste,' than they do acting upon those cultural preferences that would express their 'personal cultural identity' […] Cultural practices and preferences are produced when incorporated inherited dispositions, partialities, and competences, meet with fixed institutional or relational contexts; they are not intrinsic characteristics of the individual." Being less heterogeneous in one's actual cultural behavior would require an incredibly strict adherence to an incredibly strong taste. If the concept of habitus is to be used at all, Lahire argues, it should be considered as a compass that is both multiple and sufficiently flexible to allow people to socialize with a heterogeneous set of others and to make it easier to enjoy – or endure – bits of the culture of these others as well.

Collins (2004) takes this reasoning even further by questioning the conception of individuals as having a stable inner set of dispositions, if not identity, that remains constant across a wide range of situations at a more fundamental level. In fact, specific interactions and contexts contribute to this identity rather than revealing it. Thus, Collins (2004: pp. 82–83) argues that "taking part in an ethnic riot […] is not simply a way of acting out a preexisting ethnic identity, but a way of strengthening it, re-creating or even creating it." When evoked repeatedly, the emotions that are linked to specific contextualized roles give "rise to long-term emotional styles, which is a large part of what is meant by the term 'personality'" (Collins, 2004: p. 113). Collins' interaction ritual theory offers a promising way of understanding cultural lifestyles by taking what he calls the point of view of a radical microsociology in order to theorize the large impact of concrete interaction contexts on both the development of dispositions and the way they are translated into cultural behavior. By delving even deeper into the microfoundations of cultural socialization than Lahire, Collins lays bare the cognitive and emotional mechanisms shaping cultural lifestyles, simultaneously accounting for their thoroughly social origins as well as their profoundly contingent expressions.

Future Directions

To conclude, a few directions for future research are suggested on the basis of the ideas presented above. These pertain to searching for lifestyle differentiation among multiple hierarchies, using methods that are sufficiently exploratory to do so, and taking into account the relation between the production and reception/consumption of cultural goods and services.

Accounting for Omnivorous Lifestyles

As we have seen, cultural lifestyles are shaped by many socializing agents and institutions that neither convey consistent signals nor limit their impact to positions on a one-dimensional highbrow-popular dimension. One consequence of this is that lifestyles are unlikely to be consonant. Looking at individual lifestyle patterns, we rather observe cultural dissonance (Lahire, 2008), or omnivorousness (Peterson, 1992), as a mixture of highbrow and popular cultural genres. Although this cultural omnivorousness has been amply observed, it is still unclear how the mixing of highbrow and popular culture should be understood. It seems fruitful to study the mechanisms behind such cultural patterns. On the one hand, omnivores may appropriate a broad range of cultural styles through social mobility, where they accumulate different cultural experiences during their (typically upward) social trajectory (Van Eijck, 1999). This explanation takes into account the growing multitude of social contexts that are relevant (at different points) during people's lives. Alternatively, omnivores may be socialized into highbrow culture and subsequently learn to enjoy popular culture because

their aesthetic disposition allows them to appreciate a broad range of cultural items from a more or less formalist perspective (Lizardo and Skiles, 2012). This approach also emphasizes the different context that offers opportunities to become acquainted with cultural diversity, but puts more emphasis on the aesthetic disposition that both encourages cultural tolerance and allows for a proper decoding of cultural artifacts. Lizardo (2006) is consistent in his emphasis on cultural capital as driver of experience in his study of the impact of cultural tastes on social networks. On the same topic, Mark (1998) reasons more in line with Van Eijck (1999) by stating that sociodemographically heterogeneous networks encourage broader tastes. The latter is also more congruent with the seminal ideas developed by Lahire and Collins. In order to move beyond the assumption of habitus as the automatic or inevitable internalization of more or less homogeneous external circumstances, both suggestions advocate a closer look at the social interaction mechanisms leading to specific lifestyles.

Modeling Cultural Spaces

Cultural omnivorousness has often been linked to the notion of openness (Ollivier, 2008). According to Peterson and Kern (1996: p. 904), omnivorous taste signifies 'an openness to appreciating everything.' This may imply that omnivores differ from Bourdieu's ideal-typical snobs in that they use different criteria for deciding which cultural artifacts are of interest (e.g., Bennett et al., 2009; Johnston and Baumann, 2007), or that they apply the same aesthetic criteria to a wider range of artifacts (Lizardo and Skiles, 2012). In any case, it has become more difficult to rely on analyses that work from assumptions on the meaning of both cultural items (e.g., by constructing scales that are assumed to represent highbrow or popular culture) and socioeconomic indicators (e.g., by computing linear status scales). Studies working along these lines have shed ample light on the prevalence of omnivorousness, but have often operationalized it as the next model of cultural inequality without asking whether other models or dimensions may be at work, perhaps simultaneously. The cultural omnivore opened up one alternative for Bourdieu's theory of taste, but as the mechanisms underlying omnivorousness are only just being explored, scholars should be open to variation on more than just this (former) highbrow-popular dichotomy. There is still much exploratory work to be done in this respect and this may explain the renewed interest in Bourdieu's (1984) original method of multiple correspondence analysis (MCA) (Blasius and Mühlichen, 2010; Rouanet et al., 2000; Roose et al., 2012).

For a number of reasons, MCA can be considered a very suitable technique for a more exploratory analysis of cultural lifestyles. First, its relational approach fits well with the notion that cultural tastes and activities may (increasingly) have multiple meanings or uses (Abbott, 1988; Holt, 1997b; Lahire, 2008; Swidler, 1986). Second, it allows scholars to deal with the notion that different structuring principles seem to be at play at the same time in lifestyle formation (Chan, 2010; Holbrook et al., 2002). Third, it allows for dealing with detailed information on cultural lifestyles, possibly including tastes/dispositions and behavioral indicators simultaneously, which is required for truly exploratory purposes. Finally, it focuses on the underlying dimensions, constructing a cultural space, and thereby provides an interpretation of the findings in terms of relational differentiation that does not lean too heavily on the specific items used. This is necessary because status markers are likely to differ among societies or vary with changes in the field of cultural production (Atkinson, 2011; Van Eijck, 1999), as will be argued below.

Linking Consumption with Production

It is important to note that, for Bourdieu and others (DiMaggio and Powell, 1983; Dowd, 2011), lifestyles are not structured by social class or individual preferences alone. They represent positions in a cultural field that is largely institutionally defined. The distinction between highbrow and popular culture is also shaped by institutions (see also DiMaggio, 1992; Levine, 1988). The educational system, government, and cultural critics classify cultural products and thereby attribute symbolic value to them (Berghman and Van Eijck, 2009; Van Rees, 1987; Verboord, 2003).

DiMaggio (1987) has theorized in more general terms how such symbolic boundaries are determined by characteristics of social structures. Cultural systems vary along several analytically distinct dimensions rather than being classifiable into discrete types. DiMaggio argues that artistic classification systems differ in terms of differentiation (number of genres distinguished), hierarchy (degree of vertical ordering of genres according to prestige), universality (general vs group-specific salience of genres), and ritual strength (defense of genre boundaries by both producers and consumers). Each of these dimensions are affected by macrosocial conditions such as access to higher education, social inequality, correlations between different status attributes, or the degree of interaction between members of different classes. Also, classification systems can be defined by the ritual strength with which boundaries are separated, e.g., boundaries between the production of highbrow and popular culture. For example, Taylor (2009) argues that boundaries between popular and classical music consumption are fading as classical music is increasingly using popular culture marketing strategies such as the creation of superstars or advertising through mass media. The same holds for books, where the boundaries between literary and nonliterary genres (embodied by terms such as literary thriller or fantasy novel) are blurring due to the use of similar marketing strategies and the spread of book-related events such as award ceremonies or special book weeks devoted to literature, children's books, or thrillers. Analyzing such changing characteristics of cultural consumption is necessary to understand cultural lifestyles in a world where the boundary between state-subsidized legitimate culture production and the contemporary culture industries becomes ever more permeable.

This article is reproduced from the previous edition, volume 21, pp. 14313–14320, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

This article outlines theories of social stratification and class formation in Western thought, from antiquity to the 1960s, with a focus on Marx, Weber, and neo-Weberian approaches. It also looks at the use of concepts of social inequality and class in historiography, particularly in the *New Social History* since the 1960s, with Germany and the United States as examples. This article deals with some of the more recent approaches associated with the work of E.P. Thompson and Pierre Bourdieu among others.

This article sketches the development of theories of social stratification and class formation in Western thought, from antiquity to the 1960s, and especially since nineteenth-century sociology, with a focus on Marx, Weber, and neo-Weberian approaches. It also looks at the use of concepts of social inequality and class in historiography, particularly in the *New Social History* since the 1960s, with Germany and the United States as examples. Since then, the history of stratification and class has been fundamentally challenged and rewritten through concepts and theories of culture. Third, therefore, this article deals with some of those reformulations (e.g., E.P. Thompson, Pierre Bourdieu, or the history of consumption). Some approaches even seem to go beyond class and stratification. Here, the article discusses the impact on historical writing of gender and ethnicity research, of notions of social lifestyles and radicalized individualism, and of ideas about the cultural and linguistic 'construction' of classes.

As a universal fact of all human civilization, social inequality has been shaping advanced societies in a most fundamental way for many thousands of years, especially, since the rise of more complex cultures and political systems in the wake of the 'Neolithic Revolution.' The concept of social inequality refers to an unequal distribution of positions in society, a distribution that is determined by structures of power (e.g., the modern state and its administrative elites), of technology and economy (e.g., industrial technology and capitalism), and of cultural expression and perception (e.g., Christian religion and its attempt to define and explain a 'holy' order of worldly society).

In modern societies, social inequality is often framed as a differentiation of society in distinct groups of similar positions conceivable as 'layers' of the social order on a vertical scale. A general term for this type of social inequality structure is 'stratification.' In the Western tradition, the concept of stratification often – in a more or less explicit way – refers to a ranking of social positions according to the distribution of economic resources; the conflicting groups resulting from this are frequently called 'classes' (in a broad sense). The notion of a society divided into classes, which through their collective action fundamentally shape the dynamic processes of society, has been most widely applied to the specific historical case of Western industrial societies with their market economy, but has also been transferred from here to the description of agrarian societies in ancient or medieval times.

Since around 1970, concepts of stratification and class have been criticized for their neglect of other dimensions of social differentiation and inequality, such as gender, race, or ethnicity. Important as this recent restructuring of the debate on historical (and contemporary) modes of inequality is, stratification and class have been essential concepts for social history in the past (and appear to remain so in the future, if in a modified way). Indeed, it may be said that the development of social history as a field of historical research is hardly conceivable without the analytical concepts of stratification and class. In considering social inequality, stratification, and class in history, two perspectives may be taken. First, stratification is an empirical problem, a problem of historical subject matter. In this regard, one can follow the development of systems of social inequality throughout history, from antiquity to the twenty-first century. Second, stratification refers to an analytical and theoretical problem in (social) history; it appears as a problem of conceptualizing historical processes and structures. In this vein, one can look at concepts, approaches, and methods in research on stratification and class, and consider their development, especially since the nineteenth century, and their usage in different historiographical traditions.

This article will concentrate on the second, the conceptual level. However, both perspectives are intimately linked, since there is no empirical description of inequality without an acute awareness of concepts and language. However, for historians (as opposed to social theorists), all methodological discussion eventually points to empirical research in order to better understand systems of social inequality in the past, and therefore, in the present.

Theories of Social Stratification and Class Formation: Historical Development Through the 1960s

Even before the rise of the modern social sciences with their more elaborate theories of social structure, the explanation (and justification) of inequality was an important part of intellectual thought in advanced, literate societies, often within a general philosophical or theological context. In ancient Athens, Aristotle regarded society as consisting of three hierarchically ordered groups, among which he favored the middle, or *'mesor,'* as being most important for the stability of the *polis*.

Aristotle's scheme of 'stratification' remains influential in its attempts at defining society in terms of 'upper,' 'middle,' and 'lower' classes or strata, among which the middle class is held in highest regard (e.g., in political culture and public discourse in the USA).

In feudalist Western Europe during the Middle Ages, a different kind of tripartite scheme of inequality gained prominence: the idea of a functional differentiation of society into the three orders of Christian clergymen, noblemen, and peasants. With the rise of cities and the emergence of town burghers as an influential group, the functionalist scheme was adapted to new social realities, but it remained a central concept for the interpretation of inequality.

While these theories are themselves a subject of historical inquiry because they tell a lot about the framing and self-understanding of premodern societies (Duby, 1978), a major shift toward modern concepts of stratification and class only occurred in the late eighteenth and nineteenth centuries. In the historical and philosophical works of the Scottish Enlightenment (e.g., Adam Smith, Adam Ferguson, and John Millar), principal stages of civilizational development were associated with particular systems of social inequality and stratified class structure. The language of social inequality that is still in use, with its typical metaphors of 'class' and 'strata,' is heavily indebted to scientific discourses of the eighteenth century, and especially to the enlightenment's quest for 'classification' (Karl v. Linné) and order in the realms of both nature and culture. In the following decades, with Adam Smith and David Ricardo providing important linkages, attention in the theory of stratification increasingly shifted toward a search for the origins of inequality in economic systems of production.

The most powerful, and historically most influential, theory of class as a product of basic economic forces was for a long time Karl Marx' (and Friedrich Engels') concept of Historical Materialism, a theory according to which at each stage of society, an oppressed lower class rises against the economic and political dominance of a ruling class, and eventually overturns the old system through class struggle and revolution. Whatever critical may be said of Marx' theories and its political consequences, it nevertheless became the major reference point for most theories of inequality and stratification until the middle of the twentieth century, and possibly also thereafter. For social history in particular, it provided an extremely suggestive framework for understanding historical change in terms of economic progress, class formation, and societal conflict, instead of referring to diplomacy, politics, and the 'great men' as driving forces of history, as was the case in much traditional nineteenth- and early twentieth-century history. After Marx, theories of inequality based on functional differentiation and the division of labor played an important role for a while (e.g., with Herbert Spencer in the UK, Gustav Schmoller in Germany, and Émile Durkheim in France), but they too were primarily grounded in the idea of economic foundations of particular class systems.

At the beginning of the twentieth century, German sociologist Max Weber in some ways moved class analysis back to Marxian scope and intentions, while on the other hand he developed, if in a fragmentary manner not easy to grasp for later scholars, a broader, historically more flexible, and less dogmatic, framework for the interpretation of social inequality and class structures. Although Weber, like most of his contemporaries, under the impression of industrial capitalism's triumphant advance, acknowledged the enormous impact of economic forces on the molding of society, he was also prepared to systematically consider other dimensions of stratification. Political power, in Weber's view, often played a crucial role in determining positions in a class system; and also inequality for him appeared as fundamentally shaped by 'culture': by general interpretations of the world and the social order as, for example, provided by religion (*Weltbilder*), as well as by the honor, prestige, or status attributed to an individual (or to members of a larger group, such as a specific profession) within the normative setting of a society (see Weber, 1978).

After a brief period of neglect, Weber's concepts of social inequality and social class exerted a strong influence on both American and European social science after 1945. In postwar American sociology and political science in particular, stratification became one of the dominant topics in the field, a topic that all major 'schools' and theoretical currents had to reckon with (see Barber et al., 1968). Despite an enormous variety of approaches and methods, some common features of stratification research in the 1950s and early 1960s stand out, making them attractive for historians. Often, they were not just present-minded, but embedded in a macrosociological and historical framework of thought. Typically, they were interested in linkages between class and political power structures, and in the cultural dimensions of inequality as expressed in neo-Weberian concepts like 'status' or 'prestige' (Bendix and Lipset, 1953; Lenski, 1966).

Since the late 1950s, Weberian and functionalist research in stratification began to overlap with a renaissance of critical theories of society and inequality that were attempting to benefit from the Marxian tradition in an undogmatic manner. Authors like Ralf Dahrendorf or Anthony Giddens were widely read for their innovative intellectual combinations of Marxism and liberalism, or Marxian and Weberian traditions (see Dahrendorf, 1959; Giddens, 1973). In Western social science, the revival of the Marxian tradition proved short lived and mostly faded away in the late 1970s, leaving some strands of cultural Marxism as survivors into the then emerging new age of culturalism in the social sciences. However, Weber's influence, because of the historical depth of his work and a rare combination of flexibility and analytical precision in his categories, never quite vanished, and his work continuously remained inspiring for historians doing research on stratification and class. At the same time, Weber proved remarkably resistant against changing intellectual moods since the late 1970s and 1980s, when classical concepts of stratification and class came under attack. He thus continued to be a starting-point in some of the most important recent approaches in the sociology and social history of inequality and class.

Stratification and Social Classes in Historiography: Trends and Examples

With the rise of social history to intellectual dominance in the 1960s and 1970s in most Western countries, research on the history of stratification and class, mostly in modern societies since the Industrial Revolution of the nineteenth century,

became a central historiographical theme, and even a topic defining what the 'New Social History' was all about. In the general political and academic climate of the 1960s, with its social-democratic air and its resurgence of Neo-Marxian theories, interest for the less privileged groups of industrial society – and especially for the working class – spilled over into history and not only generated a host of special studies on stratification, mobility, and class formation, but also influenced synthetic approaches in social history and the general discourse of historians in that field. While this was a pervasive international tendency, it rendered different results within the national traditions of social history. Therefore, Germany and the US will be considered as two important examples.

Germany

With its strong methodological roots in nineteenth-century historicism and its political conservatism in the historical profession, Germany was a latecomer in the development of postwar social history, and in many respects remained dependent on the reception of theoretical innovation from other countries, such as France, the UK, and the USA. However, due to its strong traditions in social theory, and the theory of class in particular (Marx, Weber), and also because of the great historical significance of class structures in late nineteenth- and early twentieth-century Germany, topics like stratification and class formation quickly took center stage in West German social history during the late 1960s and 1970s. To a larger degree than in other countries, stratification and class emerged as the paradigmatic categories of research in social history (see, e.g., Kocka, 1975), a tendency that came under attack in the 1990s as competing concepts such as gender and ethnicity by many historians were regarded as at least equally important.

For the history of stratification and class in the 1970s and 1980s, two approaches deserve special mention. First, as was the case elsewhere, the history of classes in the beginning concentrated on the less privileged groups and lower strata of society. Here, a particular focus was on the formation of a modern, industrial working class in the nineteenth century, and on the problem of the homogenization of that class from the origins of a multitude of preindustrial, agrarian, and artisanal occupations and interests. In what he termed the 'Weberian application of a Marxian model,' historian Jürgen Kocka studied the formation of a German proletariat, which he conceived as a Marxian class in its basic socioeconomic determination, and at the same time as a Weberian ideal type with which reality can never fully correspond (see Kocka, 1980, 1987, *see* Labor History; Working Classes, History of). Class formation in this approach was considered a historical process progressing through different levels. It proceeded – ideally, though not necessarily in historical reality – from economic homogenization in the workplace toward increasing social and cultural coherence and might end with class consciousness and the political organization of the working class. Since the 1980s, class formation models have also been applied to the upper strata of German society, particularly the bourgeoisie and the professional middle classes, but it appeared that in this case, 'culture' seemed to operate as a much more influential determinant of class than a common economic position.

Second, German traditions in social theory fostered an unusually strong interest in the historical conceptualization of the overall class structure and stratification system, again with an emphasis on the period of German modernization and industrialization from the late eighteenth century onwards. In conceiving social history as the 'history of society,' and the history of society as grounded in structures and processes of social inequality, stratification, and class, German historian Hans-Ulrich Wehler in a very influential project attempted a synthesis of modern German history in terms of a history of inequality and class. His *Gesellschaftsgeschichte* in a systematic way asks for the transformation of the estate system of preindustrial society into an industrial society comprised of social classes, with the bourgeoisie and proletariat in the center, but also giving attention to the nobility and to agrarian classes, such as farmers or farmworkers (Wehler, 1987–95). Typical for much German social history in the 1970s and 1980s, Wehler's approach is methodologically under the heavy influence of Max Weber's categories; and it politically adheres to a vision of an increasingly equal, less class-rifted (if not classless) society.

While most other German authors are not as ambitious and comprehensive as Wehler in their concern with social structures, they have, however, been more inclined to expand the explanatory framework of social inequality into the realm of culture. A new focus of research is on the complicated relationship between social structure on the one hand, and cultural perceptions and practices on the other hand.

The United States

In its self-image, the US has been born as a country of equality, defined by a lack of class and stratification in the European sense, and by the predominance of a broad middle class. The fact that the US has never known an estate system of social order has indeed, in combination with the country's more pragmatist tradition in social thought, exerted a deep influence on social scientific and historical approaches toward class structure and socioeconomic inequality in America. On the other hand, critical strands in social theory and historiography, which were able to identify and discuss inequality of class, appeared earlier than in Germany and remained stronger in the first half of the twentieth century – with the 'Progressive historians' such as Charles Beard being the most important example.

During the 1960s, the blossoming of the 'New Social History,' together with a more self-critical mood in American society in general, prompted a new interest in the history of social class and inequality in America, much in the same way as in other Western countries at about the same time. With regard to approach and method, historians often concentrated on less privileged groups, such as workers and immigrants, and they often did so in case studies of particular cities and through the study of social mobility among the lower strata of urban society (Thernstrom, 1964). For some time around 1970, Neo-Marxist approaches to the study of class and 'class struggle' in American society drew some attention, but on the whole, even leftist historians of class and inequality undertook

much less theoretical effort in conceptualizing their topics than in Germany.

Similar to trends in European social history, however, quantitative methods (as in the study of social mobility) since the late 1970s lost much of their earlier appeal. Instead, the problem of class was more often approached through qualitative, even hermeneutical methods, and through the lenses of class culture and class experience. Also, outside the somewhat narrowing field of working class and labor history, the study of social classes shifted its main focus from the lower classes to the middle classes and their origins in nineteenth-century social change (e.g., Blumin, 1989; Zunz, 1990). This shift may be understood as an attempt to deconstruct the pervasive myth of the American middle class, and at the same time to historically explain the middle-class orientation of twentieth-century America.

In a broader perspective, the study of stratification and class as such after the 1970s retreated from the center of concern for social historians much more quickly, and more pervasively, than in Europe. Obviously, the most important reason for this is the existence of other, competing dimensions of inequality in American society, especially the inequality of race and ethnicity. Class formation in the US rarely occurred in ethnically homogeneous milieus, and often racial and ethnic identity turned out to be more important, and certainly of a much more durable character, than class identity and economic position.

For the same reason, synthetic efforts with generalized views on American society from the perspective of stratification and class were hardly undertaken by American historians. The one large project that probably comes closest to such a synthesis is the two-volume textbook 'Who Built America?' collectively conceived and written by the American Social History Project under the intellectual guidance of labor historian Herbert Gutman (See, American Social History Project 1989–92). The book attempts a synthesis of American history from colonial times to the present by centering its narrative around the development of social classes – particularly the industrial working class – and the struggle of less privileged groups for participation in the economic and political resources of 'mainstream' America. At the same time, the authors' efforts demonstrate that a narrative of American social history from the viewpoint of stratification and class alone cannot make sense; it needs to be expanded by, and connected with, additional categories of inequality, such as race, ethnicity, and gender.

The Challenge of Culture in the History of Stratification and Class

The discussion of the two national examples, especially the case of the US, has already hinted at important new trends in historical research that have begun to change the field in fundamental ways since the 1980s and will probably continue to do so in the future. Although many of the recent tendencies stem from similar motives – e.g., the increasing dissatisfaction with interpretations of class based on the structures of male industrial work – and therefore often overlap in historiographical practice, it is useful to distinguish two horizons of criticism and expansion of the classical stratification and inequality paradigms. Some scholars, for different reasons, fundamentally question the relevance of concepts, such as 'class' and 'stratification' and try to develop alternative concepts, or alternative theoretical and methodological viewpoints on the problem of inequality in history (see Section Beyond Class, Beyond Stratification?). Others consider 'class' and 'stratification' as still important, or even indispensable notions for social history, yet argue that they have to be redefined in order to meet the challenges of social reality and social science at the turn of the twenty-first century. This ongoing redefinition of class is in most cases centered around the idea of 'culture.' Culture, especially in the forms of 'language' and 'experience,' is now widely believed to be the prime factor in determining stratification systems and class structures. However, at a closer look, the challenge of culture differentiates into a number of theoretical and empirical approaches.

Class as Social Action, Experience, and Culture

In 1963, the English Marxist historian E.P. Thompson published his two-volume 'Making of the English Working Class,' which is arguably among the dozen most influential works in twentieth-century social history (Thompson, 1963). At that time, classical approaches to class formation grounded in systematic sociology or political science were still widely in use, and in some countries just beginning to influence the expanding field of social history. Thompson's massive study was rather conventional in the sense of its practical empiricism and its Marxian notion of a working-class winning identity and togetherness in the struggle against its bourgeois class enemy. What was new, however, was Thompson's insistence that 'class' was not a quasi-objective structure determined by certain economic forces, but a very fluid result of practical action and social experience on the part of the lower classes in the decades around 1800. As Thompson largely focused on preindustrial work and living experience, he discovered the roots of class in traditions and reinventions of popular culture. In many respects, Thompson's book was ahead of his time. Reception and debate in Germany, for example, only took off in the 1980s and turned his pioneering work into a major stimulant for the then emerging culturalist turn in social history (*see* Cultural History).

Class Experience: From Production to Consumption

Classical approaches to the history of stratification, from the enlightenment theories of a division of labor to Marx and beyond, have based their identification of certain classes, and their description of the overall inequality structure of society, on the sphere of production, and on the relative position of an individual (mostly seen as a male adult and family head) acquired in that society's system of work and employment. As the nineteenth-century fascination with factory work and industrial production faded and the twentieth century increasingly developed the self-image of a consumer economy and society, it seemed appropriate to search for social spheres of class formation outside the workplace experience: at home, in leisure activities, and especially in

consumption. In American and in British historiography in particular, the history of consumption has been one of the most significant discoveries for the field of social and cultural history in the 1990s (*see* History of Consumption), and several attempts have been made to conceptually link consumption and class, some of which build on much earlier efforts, such as Thorstein Veblen's 'Theory of the Leisure Class' with its ideas about the role of 'conspicuous consumption' for the life of the upper classes.

The notion of consumption can play a key role because of its ability to connect the perspective of economy – the appropriation of goods by groups with different economic resources – with the perspective of culture – insofar goods serve as symbols and as expressions of (individual or collective) identity and lifestyle. It also allows for a more adequate consideration of female and private-life contributions to the formation of social inequality and class. In an important empirical study on Chicago in the 1920s and 1930s, historian Lizabeth Cohen investigated the formation of class identity among ethnic workers and their families through their shared experience of consumption and modern mass culture institutions like radio (Cohen, 1990). As the history of consumption still flourishes at the turn of the twenty-first century, it is likely that its impact on the history of inequality and class will grow even larger in the near future.

Pierre Bourdieu: Class and Cultural Distinction

The first two examples for the cultural expansion of the history of class represent developments within the historical profession, yet trends and new concepts in other social scientific disciplines have also had their impact on the topic. While national traditions of thought remain influential – with Max Weber, for example, still being of prime importance in Germany, and anthropologist Clifford Geertz stimulating American debates – in international perspective one scholar's work in particular has received near unanimous attention and acclaim by social historians during the 1980s and 1990s, namely French sociologist Pierre Bourdieu's theory of class and cultural distinction as developed in his major work *La distinction* (Bourdieu, 1979).

Arguing from his research on contemporary French society, Bourdieu secures a central place in social research for the problem of inequality and even sticks to the concept of class. Yet in a brilliant way he enlarges that concept by understanding class as the result of a complex ensemble of not just economic, but also social and cultural resources or types of 'capital.' Similar to the category of 'prestige' in 1950s American sociology, Bourdieu defines an individual's position in society in terms of his or her 'distinction' and 'habitus,' a concept referring to sociocultural outlook and self-stylization. Though obviously fitting the self-oriented consumer and leisure society of the later twentieth century especially well, the appeal of Bourdieu's approach also extends to the analysis of more traditional societies in the early modern era, and even to non-Western societies, not least because of Bourdieu's own intellectual origins as a social anthropologist. As Bourdieu at the same time draws on 'classical' authors of stratification research, such as Weber and Marx, his work is extremely important in providing a bridge between the classical theoretical tradition and the more recent approaches that center around language, experience, culture, and consumption.

Beyond Class, Beyond Stratification?

While the 'culturalist turn' in the humanities has substantially expanded and reframed perspectives on stratification and class in history since around 1980 other scholars have gone a step further in arguing that the conceptual framework of stratification and class might better be abandoned altogether and replaced by alternative concepts of social order. However, that does not mean that they would deny the existence, and empirical relevance, of stratification systems and class formation under certain historical circumstances. Rather, the argument is that the category of class itself is a historical product of the nineteenth century, and that therefore the continuing conceptual primacy of class endangers the ability of scholars to recognize different lines of social division and inequality.

Gender, Race, and Ethnicity

This point has been most persuasively made by feminist social scientists and historians who have argued that the predominance of class in social history has in fact only been able to describe the male half of the social world – and even that in an inadequate manner, because class formation among male individuals (or, household heads) cannot be conceived of independent from the family and gender systems out of which the sphere of production and patriarchy grows (see Canning, 1992). In a similar way, historians of race and ethnicity have maintained that the stratification of a society in terms of individuals' economic positions never functions as an independent variable in multiracial societies, such as the US, Brazil, or South Africa – nor even in European societies which are increasingly being shaped by their immigrant populations. It has hence become almost a standard method in American, and now also in British social history, to frame the problem of social inequality in the trias of 'race, class, and gender.' In the view of many feminist historians, however, this solution is a dissatisfactory compromise, because it implicitly affirms a conceptual primacy of class by molding the two other concepts after the example of class, or as mere expansions of it (see Scott, 1986).

Therefore, the history of gender is in need of developing specific theoretical foundations out of twentieth-century social theory in order to establish itself as an independent approach in social studies, and not just a part of the 'litany of class, race, and gender' (Scott, 1986: p. 1055). In the near future, we will perhaps see more theoretical efforts, and empirical historical studies, going in that direction, not just in gender history, but also in the history of ethnicity.

From Classes to Lifestyles, 'Milieus,' and Radical Individualism

A completely different line of thought, which also calls traditional concepts of stratification and class into question, has emerged in recent sociological work on contemporary western societies in their 'postindustrial' stage. As industrial work, and

the labor and class relations so intimately connected with it, loses its central status for the definition of modern societies, these societies may no longer be adequately described as stratified class societies. The large, socially coherent and even politically self-conscious groups, such as the 'working class' are considered to be rapidly dissolving, without new, equally coherent group structures building up. Instead, social relations in modern society may be described as based on radical individualization, and a similarity of social status at best finds expression in rather diffuse social 'milieus' (see Beck, 1986; Hradil, 1987). Western societies, in this perspective, are not becoming completely leveled societies with citizens of equal material resources, but the absence of material wants, and a redefinition of the value system toward postmaterial orientations, dramatically diminish the relevance of occupational situation, income, and even class-specific consumption patterns.

As 'social inequality' (in the form of social strata and classes) was the defining element of nineteenth- and early twentieth-century societies, these authors hold, categories like 'risk' or 'information' are defining societies on the verge of the twenty-first century. Although not yet widely received in social history, these new developments in theoretical and empirical sociology will probably have a considerable impact on historical views on inequality and social structure in the future. They offer important insights into the now rapidly expanding field of twentieth-century social history, but it may also be asked whether societies before the industrial age can be interpreted beyond the classical thought system of social estate, class, and stratification.

Constructing Class, Constructing Inequality: From Economic Realism to Cultural Relativism

With the class structure of industrial societies appearing more as an historical exception rather than historical normalcy, and with the interest in the socioeconomic foundations of inequality and class diminishing, historians have become more sensitive to the relativist or constructivist character of social structure in general and of 'class' in particular. Especially in British social history, questions have been asked about the 'language of class,' that is, about the use of concepts, such as class by the historical actors themselves, who were trying to express collective self-identities by communicating new notions of social bonding. With regard to the working classes, the main thrust of this research was on political organization and political action (e.g., in English Chartism), and the objective nature of class was hardly fundamentally doubted (see Stedman Jones, 1983).

Especially in the 1990s, however, and with empirical interest somewhat shifting to the middle classes, the language approach was radicalized under the double influence of cultural and linguistic theory on the one hand, and of 'radical constructivism' in epistemology and the sociology of knowledge on the other hand. Stratification and class were now analyzed as 'imaginary' realms of communication and culture; they figured as notions that expressed 'visions' of the social order as perceived by the contemporaries, rather than realities of economic and power structure as described by social scientists and historians (see Corfield, 1991; Joyce, 1991; Nolte, 2000; Wahrman, 1995). Some of these approaches fundamentally undermine any 'realistic' concept of social inequality and class, and therefore sound like a triumphant signal for the final abandonment of any social scientific or historical study in stratification and class structures. Yet at the same time it can be argued that the language-oriented and constructivist approaches have introduced important expansions to the more traditional methods of social history. They have provided bridges between social and intellectual history and have induced historians to a more careful usage of language and concepts. Also, ironically, in devoting so much energy to the problem of class in historical language and self-consciousness, this work has also underscored the importance of inequality and class in past societies.

Conclusion

After a long period of undisputed reign as a kind of master concept in the study of present and past social structures, theories of stratification and class are now undergoing a period of substantial challenge and criticism, redefinition, and even rejection. The question may thus arise whether theoretical and empirical interest in social inequality will persist in the future, especially in the discipline of history, which is now characterized by a very pronounced shift away from problems of socioeconomic structure in favor of a history of culture, symbolism, and subjectivity.

It is almost certain that inequality, stratification, and class, will lose (and already have lost) some of their original relevance as defining ground for social history as such, when compared with the 1950–70s boom of those topics in the social sciences. In addition, the emerging intercultural debates on the history of non-Western societies may prove that concepts such as 'class' and 'social strata,' which are obviously deeply rooted in the Western tradition of thought and culture since classical antiquity, are not suitable instruments for analyzing Indian, or Central African, societies, be it past or present. As 'postcolonial theories' in the social and cultural sciences describe the 'hybrid' character of such societies, the hybridity of class and competing principles of social relations may also be a distinctive mark of their inequality structures.

On the other hand, three points may be made, which serve as a reminder for the continuing importance, not only of the general notion of social inequality, but also of more specific concepts like stratification and class. First, social inequality – whatever it is grounded on, and in whatever way it is communicated – is an anthropological feature of all human civilization, not only in the West. Second, inequality has often taken the form of a hierarchical order, or 'stratification,' of distinct groups according to their access to power, their rights, and material well-being. Moreover, the hierarchical mode of social differentiation is a widespread mark of the less advanced, less technologically and culturally complex societies in which historians are often especially interested. Third, it is hard not to acknowledge the success, and the astonishing flexibility, of the concept of 'class' for describing systems of inequality. As new and intellectually promising approaches have been developed since around 1980 that link 'culture' with 'class,' and as these approaches are now applied in empirical research, there can be

little doubt about the fact that the history of inequality, stratification, and class will retain a prominent place in the field of social and cultural history.

Abstract

When an individual's attitude, opinion, cognition, or behavior is coerced it is called 'power,' but when the change is 'voluntary' or 'unconscious' the process is called 'influence.' Social influence is exerted by institutions such as schools and mass media, 'opinion leaders,' and by groups to which people belong or feel attached. The results of empirical research indicate that influence is stronger when the sources of influence are consistent. For example, the influence of mass media is stronger when the content coincides with the opinion of one's 'opinion leader.' When there are discrepancies, the influence of mass media is limited. This explains the mechanism of 'brainwashing' or 'mind control.' However, the mode of influence not only changes attitude through persuasion. The sources of influence can control the salience of people's perception. For example, by determining what is important or what to think at the time of election, mass media and political leaders can influence people's voting behavior. Also, mass media tell people what others think, what is in fashion, and what is passé. Both humans and animals instinctively know that it is safer to belong to a group than to be isolated. Therefore, people tend to be loyal to the norms of the group to which they belong and comply with its mores. In societies where 'honor,' 'shame,' and 'face' are critical virtues, not only the group's members but also 'mere acquaintances' are a source of influence.

When an individual's attitude, opinion, cognition, or behavior is forcefully developed or changed through physical sanctions or punishment, the process at play is called 'power.' However, when the creation or change is 'voluntary' or 'unconscious' the process is called 'influence.' The term 'social influence' in the broadest sense refers to all influences that individuals receive from all types of formal institutions, other individuals, and informal groups.

Formal institutions include schools, mass media, and business corporations. This article focuses on the influence of mass media as an example of the influence of formal institutions, before going on to consider personal influence and informal group influence.

Mass Media Influence

While the influences of home and school are dominant during childhood, the influences of the mass media become increasingly more pervasive after individuals reach adolescence. When radio surged in popularity among the masses during the 1930s, it was feared that mass communications, especially radio, had a powerful and instant effect on a population's attitude and behavior. This fear was reinforced by the success of the Nazis' propaganda machine in Germany and the large-scale panic in the United States in 1938 caused by a single radio program called 'The Invasion from Mars' (Cantril et al., [1940]1966). This radio play, broadcast without any prior warning by Orson Wells's Mercury Theater on CBS, was so realistic and caused such widespread panic that some people actually thought Martians had landed on Earth and sadly committed suicide. As a result, the apparent immediate influence of mass media came to be compared to a fast-acting hypodermic injection or an atomic bomb.

Empirical research on the influence of mass media, however, gradually revealed that it could not be that overwhelmingly influential. It was found that although mass media might reinforce people's existing attitudes and opinions, or even create new ones, they could hardly convince people to change already strongly held beliefs (Klapper, 1960). It was also found that even though mass media information might reach each individual directly, its influence did not. Influence, if any, was thought to reach individuals through so called 'opinion leaders' (Katz and Lazarsfeld, 1955). This view of the mass media's weak influence, however, was later challenged by several new 'powerful media' theories.

One of these theories deals with the 'agenda-setting effect' of mass media (McCombs and Shaw, 1972). Even if the mass media's persuasive power is limited, especially in the short run, they exert a strong influence on people's perception of the salience of each issue. There are 'good news' and 'bad news' stories for everybody and for every organization. If the mass media persistently play up the 'bad news' events surrounding some political candidate or party, it will affect the readers' or viewers' attitudes, and thereby the result of an election. In such a case, the mass media are not actually persuading their readers or viewers to change their minds; they are merely taking advantage of conventional social norms and reinforcing existing attitudes. Nevertheless, mass media can influence individual behavior (such as voting) by setting the priority of people's attention in regard to the issues that are being debated.

Another important role of mass media is that they tell their readers or viewers what other people are thinking. In other words, mass media inform their audience what the prevailing 'public opinion' is regarding each issue. In doing so, mass media tend to amplify the opinions they support. In an extreme case the mass media might treat a minority opinion as if it were that of the majority or some new ineluctable trend. As a result, the holders of the minority opinion, supported by the mass media, become louder and more strident while those of the majority opinion lose their voice and fall increasingly more silent. Thus, through the 'spiral of silence' mechanism orchestrated by mass media, the majority opinion

comes to be replaced by that of the minority (Noelle-Neumann, 1984).

Personal Influence

The 'opinion leader' mentioned above refers not only to professional opinion makers such as journalists, critics, and university professors but to all men and women who influence others around them on a daily basis, in some specific area, such as local politics, fashion, sports, travel, medical care, or even cooking. These opinion leaders are often asked for advice by people who look up to them. To meet such expectations, they expose themselves to the mass media more extensively than their followers. Opinion leaders compare and evaluate opinions and information that are first presented by the mass media. As a result, the influence of mass media first takes place among opinion leaders who in turn regurgitate their latest batch of news to their followers in the form of guidance or advice. Even if a person's opinion is shaped by the mass media, that opinion may be quickly replaced by that of an opinion leader because such people's opinions are trusted more by their followers than are those of the mass media. This process is called the 'two-step flow' of social influence (Lazarsfeld et al., [1944]1968).

Another explanation for this 'personal influence' is provided by the 'cognitive consistency theory.' According to this theory, people are affected by those whom they like because the cognition that one likes someone and the cognition that one's opinion is different from theirs is psychologically inconsistent and therefore uncomfortable. In such a case, it is predicted that people would change their opinion of, or attitudes toward, the person in question (Festinger, 1957; Heider, 1958; Newcomb, 1953).

One of the central studies of social influence was carried out by Milgram (1963). He examined the degree to which individuals could be persuaded to administer 'electric shock' to another person under experimental conditions. The shock was not real, but the compliance to the commands of the experimenter was very real. This study was controversial, and the subject of numerous replications (Quiamzade and Mugny, 2009) and reviews (see Blass, 2004). The effect appears to be robust across cultures (Pascual et al., 2012).

Group Influence

It is known that people tend to conform to the group that they belong to, participate in, or even just happen temporarily to be part of. In other words, the group tends to influence its members. There are several reasons for this conformity. One of them is that other people's behavior in the same group often functions as a stimulus or reminder. For example, if one sees other group members starting to eat, one feels hungry. Another reason is 'fear of isolation.' Not only humans but also many animals know almost instinctively that it is safer to be with the group than to be isolated. The atavistic 'fear of isolation' may be primitive and instinctive but makes sense. It is highly probable that to be isolated costs much more in terms of survival than it would to behave as a group member because, generally speaking, the group has far more information, experience, knowledge, and wisdom than each individual member. There really is safety in numbers.

It is for this reason that each individual usually has several 'reference groups.' 'Reference groups' are similar to 'opinion leaders.' Individuals are loyal to the norms, opinions, and inclinations of their reference groups. These reference groups may be their families, companies, local communities, or governments. Sumner's (1906) notion of an 'in-group' or 'we-group' is a typical example of the 'reference group.' While individuals are loyal to the 'in-group' or 'we-group' they tend to be indifferent or sometimes hostile to the 'out-group,' 'they-group,' or 'othersgroup.'

Social Influence Has Been Examined

Some Japanese sociologists and social psychologists think that what functions as social pressure or constraint on each individual is caused by an abstract social construct called *seken* rather than the influence of specific groups. According to them, individuals are conscious of three different kinds of 'societies.' The first is *miuchi* or *uchi*, which originally meant immediate family but can be applied to close relatives and other immediate-familylike small groups. The second is *tanin* or *soto*, meaning 'others,' 'outsiders,' or 'strangers.' This is not the same as Sumner's 'out-group' because *tanin* is not by any means recognized as a group or a collection of groups. People may be indifferent to *tanin* but are not hostile to it (unlike Sumner's 'out-group'). Finally, *seken* literally means 'world' or 'society.' Specifically, this is the area between the 'immediate family' and the 'others.' This area consists of people whom you know and who know you (other than immediate family members). Friends, neighbors, acquaintances, and relatives are examples.

An important concept used to explain social pressure and constraint is that of shame. Before whom do people usually feel ashamed? People do not feel ashamed before strangers. People do feel ashamed before their immediate family members, but they know that family members will eventually understand and forgive them. It is of *seken* that people are most afraid. *Seken* will remember failure, scandal, or misconduct for a long time and will not forgive as easily as immediate family members might. *Seken* may seem to refer to 'reference groups' but these are different because *seken* is not a group or a collection of groups and people are not always loyal to *seken*.

The same is true of 'keeping face.' Where do people 'lose face'? It is in *seken*. Therefore, individuals are always concerned with *sekentei*. There is no equivalent single word in English, but *sekentei* refers to how your friends, neighbors, acquaintances, and relatives think of you. Thus, according to Japanese sociologists and social psychologists, *sekentei* is a powerful source of social pressure and a ubiquitous constraint on individual attitudes and behavior (Inoue, 1977). This theory may be more applicable to collectivistic societies (where human relations are more important) than to individualistic societies. But even in individualistic societies people do have a sense of 'shame' and 'face,' so this Japanese theory should be helpful in explaining, at least in part, the causes and effects of social influences in individualistic societies too.

Abstract

Social influence involves intentional and unintentional efforts to change another person's beliefs, attitudes, or behavior. Unlike persuasion, which is typically intentional and requires some degree of awareness on the part of the target, social influence may be inadvertent or accidental. Social influence often operates via peripheral processing. Hence, the target may be unaware of the influence attempt. Unlike compliance gaining, which is usually goal directed, social influence is often nongoal directed and the outcomes may be inconsistent with, or unrelated to, a communicator's goals. Social influence encompasses such strategies as indebtedness or reciprocity, commitment, social proof, liking and attractiveness, authority, and scarcity.

Introduction and Definition

Social influence is a fact of everyday life. Humans are, after all, social creatures who spend a good deal of their time trying to influence one another as well as resist each other's influence attempts. Not only is social influence a ubiquitous feature of everyday interaction, it is also prevalent in the boardroom, the courtroom, the classroom, and many other walks of life. As Dahl notes, "social influence is incredibly broad, covering everything from mere presence effects and mimicry to more direct forms of social persuasion" (p. iii). Forsyth (2013) conceptualizes social influence as "interpersonal processes that change people's feelings, thoughts, or behaviors" (p. 305). Social influence may be defined as intentional or unintentional communication that produces change(s) in another's attitudes, beliefs, intentions, motivations, or behaviors. Pratkanis (2007) further adds that social influence is noncoercive in nature. Influence does not involve force.

The term communication is used broadly here and encompasses not only nonverbal cues and physical artifacts (such as clothing and the layout of a room), but cultural norms and socialization processes as well. Change(s) produced via social influence may not be immediately apparent. Because exposure to influence attempts may grow on people, a delayed reaction may occur. As Mason et al. (2007) note "influence models that address only a single time point are limited because influence is an inherently dynamic process—particularly when one takes account of the reciprocal and multidirectional influences that can occur among multiple sources and targets" (p. 281).

Social Influence, Persuasion, and Compliance Gaining

Social Influence versus Persuasion

To fully understand the nature of social influence, it is important to distinguish it from other closely related concepts, such as persuasion and compliance gaining. Persuasion is most commonly viewed as an intentional effort to alter another's attitudes, beliefs, or behaviors (see, for example, Perloff, 2014: pp. 18–19). While inadvertent influence is possible, then, 'accidental' persuasion is not. Some scholars also argue that persuasion requires the conscious awareness of the persuadee (Simons and Jones, 2011). In contrast, social influence does not require the awareness of the target(s) of an influence attempt. Some also argue that for persuasion to occur there must be an observable, measureable effect. Others disagree, noting that effects can be difficult to measure, may not be immediately apparent, and may not be what the persuader originally intended (Gass and Seiter, 2014). Psychological reactance or a 'boomerang' effect, for example, may occur. Research on social influence also emphasizes effects, but there may be latency effects involved. Furthermore, because individuals often use multiple influence tactics simultaneously, it may be difficult to isolate the effects of a particular strategy.

Social Influence versus Compliance Gaining

Compliance gaining is viewed by almost all scholars as an intentional effort to change another's behavior. Compliance gaining is usually other directed. Compliance gaining is also goal directed and results oriented. As its name implies, the emphasis is on compliance or behavioral conformity to the message recommendations. Less emphasis is placed on cognitive changes within the receiver. Like compliance gaining, social influence is other directed. Influence tactics are designed to produce changes in others, although intrapersonal influence may also occur. Unlike compliance gaining, social influence is often nongoal directed and the outcomes may be inconsistent with, or unrelated to, a communicator's goals. For example, a child may model a parent's bad behavior, such as swearing or smoking, contrary to the parent's wishes. With these distinctions in mind, social influence may be seen as an umbrella term that encompasses both persuasion and compliance gaining. Social influence can take place unintentionally or tacitly, may operate at a low level of awareness or without the conscious awareness of a receiver, and the effects of such influence processes may not be readily observable.

Origins of Social Influence Research

Social scientific research on persuasion dates back to Gordon Allport (1935) and Carl Hovland's Yale Attitude Research Program (Hovland et al., 1953). Studies on social influence date back at least 50 years, although they were not integrated

under the rubric of social influence until the 1980s. In this regard, Smith et al. (2011) observed "it is interesting to note that many of the classic studies in social psychology are, at their core, studies of social influence" (p. 599). Research on compliance gaining is more recent and can be traced to Marwell and Schmitt (1967) and Wiseman and Schenck-Hamlin (1981). Research on social influence spans a number of fields including communication, psychology, social psychology, sociology, consumer behavior, and behavioral economics, among others. Studies in this area have examined a wide range of topics including conformity, social proof, normative influence, modeling of behavior, mimicry, psychological reactance, and psychological commitment, to name but a few.

Processes of social influence finally coalesced with the publication of Robert Cialdini's landmark text, *Influence: Science and Practice*, in 1984. The legitimacy of the field of study was established more firmly in 2006 with the launch of the journal *Social Influence*. Although some studies have explored the neurological bases of social influence (Izuma, 2013), the focus here is on communication phenomena – both messages and behavior – that facilitate influence.

Theoretical Frameworks

A number of dual processing models maintain that messages are processed via one of two routes. Central processing (Petty and Cacioppo, 1986a,b), or what some refer to as systematic processing (Chaiken and Trope, 1999) is thoughtful, effortful, and deliberative. Receivers who rely on central processing scrutinize message content carefully. The alternative route, peripheral processing (Petty and Cacioppo, 1986a,b), or what some call heuristic processing (Chaiken and Trope, 1999) relies more on mental shortcuts. Receivers who default to this route tend to respond reflexively to messages. Although receivers may use both routes at once, they typically favor one over the other. Peripheral processing is closely related to what Cialdini calls automaticity, whereby people exhibit knee-jerk reactions that are quick and efficient, but often lead to poor decisions. Simple language triggers, such as the words 'free' or 'save,' for example, may trigger impulse purchases by consumers.

Social influence often takes place via peripheral processing. When people have low involvement or little motivation to pay attention to an issue, they tend to rely on mental shortcuts and superficial thinking. They are less thoughtful and more likely to respond based on appearance cues or social norms. The mere presence of other persons, for example, may make watching a comedian more funny or viewing a sporting event more exciting. Individuals often rely on heuristic cues. A consumer, for example, might assume that the more expensive of two items must be of higher quality. A voter might decide a political candidate is credible based on the candidate's attractiveness. A good deal of social influence, therefore, takes place at a low level of awareness. For example, males rated a female who was wearing a red blouse as more sexually attractive than the same female wearing a blue blouse (Elliot and Niesta, 2008). Color functioned as a peripheral cue in their ratings. As another example, customers in a wine shop purchased more French wine when French music was playing in the background and more German wine when German music was playing (North et al., 1999). Background music thus served as a peripheral cue that activated wine preferences.

In addition to dual processing models, a variety of other theories and models help to account for social influence effects. These will be discussed in relation to particular strategies and tactics, beginning with those identified by Cialdini.

Cialdini's Principles of Influence

In some respects, Robert Cialdini can be credited with founding social influence as a field of study. Although, he did not conduct the original studies, he was the first to systematically integrate research from a variety of disciplines under the heading of social influence. Cialdini (2009) identified six core principles of social influence which are outlined here.

Reciprocity

When one person performs a favor for another, the other person feels obligated to return the favor. One good turn deserves another, as the saying goes. According to Cialdini, this proclivity to reciprocate favors is culturally universal. Performing a favor or giving someone a gift – even if the favor or gift was not requested – creates a sense of obligation or indebtedness in the recipient. Initially, the target may be unaware of the social *quid pro quo*. What is more, such pregiving can result in unfair exchanges. The source enjoys the advantage of deciding on the initial favor as well as the return favor. A neighbor, for example, could retrieve another neighbor's trash cans from the curb on trash day. A few days later, the helpful neighbor might ask to borrow the second neighbor's lawn mower. As the recipient of the uninvited favor, it would be harder for the second neighbor to say no. Similarly, a wealthy voter might make a sizable campaign contribution to a candidate. The donor would not necessarily be buying the candidate's vote, but if the candidate won, the donor could expect some sort of return favor, whether it was a simple photo opportunity, a sit-down meeting, or support for a particular piece of legislation. The norm of reciprocity is a powerful tool for influence. Once established, a social 'I owe you' (IOU) can be difficult to resist without seeming ungrateful or ill-mannered.

Commitment and Consistency

People like to think that they are consistent in their beliefs, attitudes, and behaviors. It bothers them to say one thing and do another. They also do not want to be perceived by others as hypocritical. The need for consistency is partly a psychological drive and partly a social desire to maintain face. When a person perceives that his or her attitudes, statements, or actions are in conflict, the person is motivated to reduce the perceived incompatibility. The person might go about doing this in a variety of ways, including denial, bolstering, rationalizing, differentiating, or other techniques designed to reduce angst.

Public commitments are more binding than private commitments. Hence, wedding rituals such as engagement rings, wedding announcements, public vows, and wedding receptions increase the likelihood that the bride and groom will follow through with the nuptials. Commitment contracts and

devices, such as New Year's resolutions, chastity rings, or swear jars are also ways of increasing an individual's adherence to a particular form of conduct. Cialdini notes that commitments often 'grow legs,' meaning that once a person decides on a particular course of action she or he will persist on that path even if the original motivation for doing so no longer exists.

Social Proof

People often exhibit a herd mentality. When they are unsure of how to behave in social situations, they often look to others as guides for behavior. For example, women in a cafeteria line were much more likely to select a dessert if the person ahead of them did so (Guarino et al., 1994). Social proof also operates online. An initial positive or negative review by one user can bias subsequent reviews (Muchnik et al., 2013).

The more ambiguous the situation, the more likely an individual is to rely on social proof. The more credible the model, the more likely others will follow his or her lead. Following another's lead is also more likely, if the modeler perceives she or he is similar to, or identifies with, the model. Celebrities, peers, groups, or individuals may serve as models. For example, studies show that adolescent exposure to on-screen smoking in movies significantly increases the likelihood that teens will take up smoking (National Cancer Institute, 2008).

Social proof can be informational, based on a desire to be accurate or correct. A person who knew little about fishing, for example, might observe what other anglers were using for bait. Social proof can also be normative, based on a desire to be accepted or fit in. A new employee, for instance, might adapt his or her clothing style to what other employees were wearing.

Word of mouth (WOM), which plays an important role in online marketing, relies on social proof. Consumers often look to others' opinions when deciding what movie to see, where to dine, or what brand of electronics to buy. Online reviews now figure heavily in the decision-making process. A number of Web sites depend on such consumer reviews. Liking a post on Facebook, retweeting another's tweet, or sharing a photo on Pinterest are all forms of online electronic WOM. Social norms marketing, which is used in public awareness campaigns, also relies on social proof. Social network marketing (SNM) seeks to correct people's misperceptions of what is normal or typical behavior, thereby promoting more healthy or safe behavior. College students, for example, often hold misperceptions about alcohol consumption, overestimating the amount of drinking that occurs on campus. Correcting such misperceptions has been shown to reduce binge drinking (Turner et al., 2008).

Liking/Attractiveness/Similarity/Ingratiation/Immediacy

Liking is a pervasive tool for influence. All else being equal, we are more likely to comply with a request by someone we like than someone we dislike. Liking operates in the workplace, in social groups, in retail sales, in doctor–patient interactions, and with complete strangers. As with other influence strategies, liking operates primarily via peripheral processing. Liking may be established in a variety of ways. Perceived similarity is one. We tend to like people who we perceive are similar to us. We identify with people who have similar tastes and interests.

Nonverbal cues are another. Peter Andersen's Direct Effects Model of Immediacy (2004, 2007) posits that nonverbal immediacy behaviors, such as eye contact, smiling, leaning forward, standing closer, and light touch convey warmth and friendliness. Such warm, friendly behaviors facilitate influence attempts. Other research shows that nonverbal mirroring, e.g., mimicking another's nonverbal behavior, can increase rapport, liking, and perceived similarity which, in turn, enhances influence (Guéguen, 2009).

Authority

Authority figures enjoy a decided advantage when it comes to influencing others. Milgram's (1974) classic study demonstrated just how much influence authorities command. When an experimenter, dressed in a white lab coat, holding a clip board, instructed participants to administer increasingly stronger shocks to a stranger in another room, 63% of the participants complied, even though some levels of shock were labeled 'Danger: Severe Shock.' That the participants perceived the experimenter as possessing expert and legitimate authority goes a long way toward explaining the results (Blass and Schmitt, 2001).

Sources who are perceived as being highly credible are more influential than those who are not. Credibility is a perceptual phenomenon; it exists in the eye of the beholder. It is also situational. A person with high credibility in one communication context may lack credibility in another setting. Examples of influential sources abound. Celebrities hold sway over the public, which is why they often land lucrative endorsement deals. Their statements are liked, followed, shared, and retweeted by an admiring public. Politicians also exert leverage on voters. To be sure, not all politicians are revered, but elected officials have considerable clout. Economists, journalists, judges, medical experts, and scientists also wield a good deal of influence.

According to Cialdini (1984), an overreliance on authorities can lead to 'blind obedience' whereby decisions are made without scrutiny and orders are followed without question. The abuse of detainees at Abu Ghraib prison in Iraq exemplifies this tendency. Low-level guards forced detainees to perform degrading acts after being told by higher ups in the chain of command to soften up prisoners for interrogation (Hersh, 2004).

Scarcity

According to the laws of supply and demand, that which is rare is all the more valuable. That which is *perceived* as scarce is also more prized. We want what we cannot have. The scarcity principle is based on this tendency of human nature. It is why advertisers peddle goods with phrases like 'must act now,' 'limited time offer,' or 'limit one per customer' (Aguirre-Rodriguez, 2013). It is why ticket scalpers are able to sell tickets for many times their face value. Scarcity explains why people belong to exclusive groups or clubs, why art prints are sold as 'limited editions,' and why daters often play 'hard to get.' The prospect of not getting what we want, or losing what we already have, creates a sense of urgency. One theoretical explanation for scarcity's effectiveness is based on

psychological reactance (Brehm, 1966) or what is often called 'reverse psychology.' The threat of losing a freedom, having a choice usurped, or foregoing an opportunity triggers defensiveness and a sense of urgency. A quick choice or purchase alleviates the threat.

Scarcity appeals take two forms: limited quantity scarcity (LQS) and limited time scarcity (LTS). An example of the former is a study by Worchel et al. (1975) who found that consumers who were asked to rate a cookie rated it more highly, if it was only one of two left, rather than one of 10. Scarcity may also depend upon limited time. An LTS strategy establishes a limited time 'window' for acting. Either approach can trigger inferences about product quality, price, uniqueness, or desirability. Black Friday sales rely on both strategies; a limited numbers of items are on sale for a limited amount of time. Evidence suggests that LQS appeals prompt a greater sense of urgency and foster stronger purchase intentions than LTS appeals (Aggarwal et al., 2011).

Other Social Influence Strategies

In addition to the six core principles identified by Cialdini, there are many other strategies from which an influencer may choose. Anthony Pratkanis (2007) has compiled an index of 107 social influence tactics, which he groups into four broad categories. One category consists of strategies that seek to establish a favorable climate for influence, the second seeks to foster a favorable relationship with the target, the third focuses on message structure and organization, while the fourth category relies on emotion-laden appeals. Although, there is not sufficient space to discuss each strategy here, some highlights and exemplars from each of the four categories are provided.

Landscaping

Landscaping, the first of Pratkanis (2007) four categories of social influence, involves laying the groundwork for a successful influence attempt. Pratkanis and Aronson (2001) also refer to this approach as 'prepersuasion.' This group of strategies seeks to create a favorable climate for influence. The time, place, or setting is selected to make the target more receptive to an entreaty. A beau who selects a romantic setting in which to 'pop the question' is using landscaping. An employee who shows up early for work each day before asking the boss for a raise, would be engaged in landscaping. Pretrial publicity or the 'spin,' an attorney puts on a client's case is an example of legal landscaping. Some specific examples of this strategy are identified next.

Defining and Labeling an Issue

One means of influencing people is through the power of labeling. An influencer who uses labels effectively can load the dice in his or her favor. For example, referring to a political figure as a 'wonk,' 'pundit,' or 'hack' automatically casts the politician in a negative light. Similarly, assigning idealistic names to legislation, such as the 'Clear Skies Initiative,' or the 'Affordable Health Care Act' imbues the bills with positive connotations. Influencers can also seize the moral high ground via naming and labeling of issues. The term, 'pro-life,' for example, implies that opponents are 'antilife,' while the term 'pro-choice' suggests opponents are 'antichoice.'

In the interpersonal arena, the use of positive social labels ('you are so helpful,' 'I knew I could count on you') can facilitate compliance with requests (Goldman et al., 1985; Kraut, 1973). This is consistent with Becker's labeling theory, which suggests that people tend to live up to the labels assigned them, and with Bem's self-perception theory, which maintains that individuals infer who they are based on what they do. Labeling can increase the likelihood that an individual will draw the inference about him or herself that a persuader intends.

Limited Choices or Options

Another method of 'stacking the deck' in one's favor is to limit the number of options presented. A parent who wants to put a child to bed could issue a directive, "Brush your teeth, then I'll read you a story, then it's your bedtime." Such a dictatorial approach, however, might trigger defensiveness. Offering a choice, such as "Would you rather brush your teeth first, then have a bedtime story, or have a bedtime story, then brush your teeth before bedtime?" gives the child a say in the matter. The options are limited, but the child is less likely to perceive the choice as an infringement on his or her freedom.

Credibility and Social Relationships

The second category of social influence strategies identified by Pratkanis (2007) involves source factors. The reputation of a source and his or her ability to cultivate positive relationships are key to the effectiveness of influence attempts. Source factors are closely related to the twin concepts of authority and liking identified by Cialdini (1984). Two variations on source factors are presented next.

Source Credibility

Source credibility, or *ethos* as it is also known, may well be the most robust form of social influence there is. By way of illustration, a study by Guéguen and Pichot (2001) found that pedestrians were more likely to ignore a 'no crossing' light and follow a well-dressed (high-status) person through an intersection than a poorly dressed (low-status) person. Similarly, shoppers in a music store were less likely to confront or report a well-dressed person who shoplifted (10% intervened) than a shabbily dressed person (39% intervened) (Guéguen, 2003). Credibility is a perceptual phenomenon, e.g., it exists in the eye of the beholder. Credibility is also multidimensional and comprised of three primary dimensions: competence, trustworthiness, and goodwill. Sources who exhibit these dimensions, especially perceived expertise or competence, enjoy significant advantages over their less credible counterparts when it comes to social influence (Pornpitakpan, 2004). The advantages enjoyed by credible sources are accentuated when a target relies on peripheral, rather than central, processing. This is because a person who defers to a source is less likely to pay attention to message content. In contrast, when a source is perceived as lacking in expertise or being untrustworthy, the target is more likely to scrutinize the content of the message.

Plain Folks Appeal

Rather than emphasizing source expertise, an influencer may employ a 'plain folks' appeal. This strategy, also known as a 'common man' appeal, portrays the source as an ordinary person, not a snob, an elitist, or a member of a privileged class. A 'plain folks' appeal may disparage evidence in favor of 'common sense.' What this strategy gives up in the expertise dimension, however, it makes up for in the trustworthiness dimension. A target may identify or empathize more closely with an 'average Joe or Jill' based on perceived similarity. Tom Bodette, the spokesperson for Motel 6, exudes such folksiness when he recites the company motto, "We'll leave the light on for you." Politicians cast themselves into the plain folks role when they don a hardhat at a factory, roll up their sleeves at a country fair, or enjoy a beer at a local watering hole. Voters may see them as more genuine or authentic for doing so.

Message Tactics

A third category of social influence strategies identified by Pratkanis (2007) focuses on message structure and organization. Here the emphasis is on adapting the content of the message to increase its appeal. Many of these strategies, such as implicit versus explicit conclusions, one-sided versus two-sided messages, primacy versus recency, distraction, forewarning, and inoculation comprise the 'bread and butter' of traditional persuasion research. Since explanations of these more traditional strategies are readily available elsewhere, the strategies discussed next are somewhat less well known.

Self-Generated Arguments

When we think about social influence, we tend to think about one party, the source, influencing another party, the target. There is another way, however, which is to have the target convince himself or herself. Self-generated arguments are effective because the target is an active participant in the process. For example, Gregory et al. (1982) gave some residents in a neighborhood reasons for subscribing to a cable service. Other residents were asked to imagine their own uses for the cable service. The results showed that roughly one in five (19.5%) of the residents who were supplied with reasons wound up subscribing, whereas almost half (47.4%) of those who came up with their own reasons subscribed.

Self-generated arguments can be proattitudinal in nature, reinforcing a person's point of view, or counterattitudinal, such as when a person plays the role of devil's advocate. Gordijn et al. (2001) found that proattitudinal advocacy was more effective when an advocate believed his or her position reflected the majority view. Conversely, counterattitudinal advocacy was more effective when an advocate believed his or her position represented the minority view.

Several explanations for the effectiveness of self-generated arguments have been offered. One is that active participation involves central processing, which tends to produce more attitude change than peripheral processing. Another is that when people are asked to develop arguments designed to persuade others, they generate arguments that they find most convincing to themselves. A third explanation is based on cognitive dissonance. Counterattitudinal advocacy, e.g., playing devil's advocate, arouses dissonance leading to attitude/behavior change in the direction of the position advocated.

Message Discrepancy

How much should the position advocated by a source differ from that of the target? If a source's stance on an issue is identical to the target's position, no attitude or behavior change will occur. If the source's stance is radically different from the target's position, the message may be rejected outright. The challenge is to strike a balance between asking for too little change or too much. Social Judgment Theory (Sherif and Sherif, 1967) addresses this issue. Message discrepancy refers to the degree to which a source's position differs from the target's position on an issue. A target's preferred position on an issue is called her or his anchor. The range of positions surrounding a person's anchor that are perceived as tolerable represents that person's latitude of acceptance (LOA). The range of positions that depart so much from the person's anchor that they are deemed unacceptable represents the person's latitude of rejection (LOR). There may be buffer zones as well, known as latitudes of noncommitment (LNC). LNCs are positions about which a target is neutral or, perhaps, indifferent.

For maximum influence, a source should design a message to be as discrepant as possible from the target's anchor, without falling into the target's LOR. The assimilation-contrast phenomenon predicts that messages that fall inside a target's LOA or LNC will be assimilated and perceived as closer to the target's anchor position than they really are. Messages that fall within the target's LOR tend to be contrasted and perceived as farther from the target's position than they really are. By way of illustration, Siero and Jan Doosje (1993) presented Dutch drivers with messages about trade-offs between automobile use and the environment. They found that a moderately discrepant message, e.g., one that fell within the motorists' LNC, produced more attitude change than mildly or moderately discrepant messages.

Emotional Tactics

The fourth category of social influence tactics identified by Pratkanis (2007) involves emotional appeals. Emotional appeals are designed to evoke positive or negative affect. Livingston maintains that "people buy for emotional reasons, then justify their purchases with logic" (p. 16). Typically, emotional appeals function as external inducements. They supplement, or substitute, emotion for reason as a means of changing a target's attitudes or behaviors. Emotional appeals come in a wide variety: embarrassment, empathy, fear, humor, guilt, ingratiation, patriotism, pity, pride, sex, and more.

Ingratiation

Ingratiation has been practiced for millennia. Ingratiatory behaviors are designed to instill positive feelings in a target. "Hey, boss," a flatterer might say, "you look great. Have you lost weight lately?" Watt (1993) found that ingratiators were perceived by their supervisors as being more competent, more

motivated, and more qualified for leadership positions than their noningratiating counterparts. Although, people frown on the use of ingratiation – consider all of its pejorative nicknames: buttering up, brownnosing, bootlicking, sucking up – it is still a common and effective tactic for influence. Chan and Sengupta (2010) found, for instance, that ingratiation is still effective even when a target suspects the ingratiation is insincere. Ingratiation's effectiveness is based partly on liking ("I love your new haircut"), partly on perceived similarity ("I'm a Cubs fan too!"), and partly on social labeling ("You are so thoughtful").

Fear Appeals

Fear appeals are a staple of social influence. They are a fixture of public service announcements and political campaigns. For some parents, they are the bread and butter of child rearing. Some commentators suggest that we are living in a 'culture of fear' and that fear-mongers try to keep the public in a perpetually fearful state. Kim Witte's (1992) Extended Parallel Processing Model is based on a dual processing model. Danger control facilitates constructive responses, while fear control triggers maladaptive behaviors, such as panic. The most effective fear appeals combine high levels of perceived threat with high levels of perceived efficacy. Threat level hinges on the perceived probability, severity, and immediacy of a threat, along with the target's perceived susceptibility or vulnerability to the threat. Efficacy involves both perceived response efficacy, or the availability of a viable means of avoiding the threat, and perceived self-efficacy, or the practical ability of the target to take the recommended action.

Conclusion

To influence is human. Social influence permeates nearly every aspect of daily life. No single chapter can hope to cover all the ways in which people influence one another. This article has provided an overview of some of the most well known, frequently cited forms of influence.

A strength of social influence research is that much of it has been conducted in naturalistic settings. Another strength is that outcome measures have often included naturalistic measures. A third strength of social influence research is that has yielded a wealth of useful, albeit qualified, generalizations, including a number of counterintuitive findings.

An important contribution of research on social influence has been to reveal the variety of ways in which people are swayed implicitly, with little or no awareness. Some may find it disconcerting that humans are not that rational after all. We can blink, sway, and nudge one another into doing things. This realization, however, makes learning about social influence more vital than ever.

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social innovation refers to the processes and outcomes that develop a novel approach to addressing a social problem or need. Compared to commercial innovation, it poses some distinctive challenges, particularly with regard to the incentives to invest in it, assessment of performance, and diffusion of effective innovations. Scholars began paying attention to this phenomenon in the late twentieth century, but many open research questions remain.

The term 'social innovation' has had two meanings in the academic literature. In its earliest scholarly uses, primarily in sociology, it was used to refer to the creation of new patterns of human interaction, new social structures, or new social relations. The second focuses on innovations designed to address a social or environmental issue or to meet a specific *social* market failure or need. Often, both types of innovation are combined to establish new patterns of social relations that have positive social outcomes. As Mulgan et al. (2007) argued, social innovations are "social both in their ends and their means" creating "new social relationships and collaborations" as well as responding to specific social needs (p. 2). This article provides an overview of the evolving field of social innovation globally. First, it introduces the term and sets out key definitions. Next, the chapter explores the key contexts and drivers of social innovation and maps the actors who engage with it. Following this, social innovation is located within academic theory. The next section considers some of the distinctive challenges faced by social innovation. The concluding section makes some final observations and sets out a future research agenda.

Introduction

Innovation designed specifically to address social or environmental issues is not new. However, it is only recently that research, deliberative practice, and the formulation of bespoke policy agendas focused specifically on such 'social innovation' have begun to emerge. Today, social innovation is increasingly seen as essential in developing the 'clumsy solutions' needed to tackle today's complex 'wicked problems' across the world (Mulgan et al., 2007; Murray et al., 2010; Nicholls and Murdock, 2011).

Mainstream analyses of the emergence of innovation at the country level have often identified a series of 'waves' based on technological change, usually starting with the Industrial Revolution in the eighteenth century (Kondratiev, 1998). In essence, five waves of modern macroinnovation have been discerned so far, each associated with a particular disruptive technology in the Schumpeterian sense:

- The Industrial Revolution (1771–1829)
- The Age of Steam and Railways (1829–75)
- The Age of Steel, Electricity, and Heavy Engineering (1875–1908)
- The Age of Oil, the Automobile, and Mass Production (1908–71)
- The Age of Information and Telecommunications (1971–)

These waves are usually characterized by step changes in financial markets, productivity growth, urbanization, mass production, knowledge intensity and transfer, and per capita income growth. In other words, *economic* factors are used as the primary evidence in defining such waves of innovation, with social or societal factors being subsidiary or external to the main patterns of disruptive change discerned. More recently, however, *social* innovation has been recognized as a new wave of innovation that gives primacy to systems and processes of change in social relations on the one hand and, on the other, to innovation around the conceptualization, design, and production of goods and services that address social and environmental needs and market failures. Social innovation may represent a step change compared with previous waves of innovation in that it often attempts to disrupt and reconfigure systems themselves rather than simply providing disruption within existing systems. Social innovation can be seen as the simultaneous production of new ideas and new social structures *and* a process of recontextualization of the norms of the public good, justice, and equity.

Today, social innovation cuts across all sectors of society often combining the conventionally disparate logics of private, public, and civil society in new, hybrid organizations and forms of action. For the private sector, there are two dimensions of social innovation: first, the recognition that technological innovations fail if they are not integrated with changes in social relations within the organization and second, as a new agenda for the role of business in society. For the state, social innovation reflects an established tradition of welfare reform based on increased efficiency and effectiveness. It may also challenge the governance status quo in societies by aiming to transform the power structures across social relations that allocate goods and services ineffectively or unequally. For civil society, social innovation involves both internal process of organizational change (such as new legal forms and collaborations) and novelty in external outputs and outcomes (such as new products and services).

[†] Deceased. After a long illness that he had bravely fought, Professor J. Gregory Dees died suddenly on 20 December 2013. With Greg's death, the academic field of social entrepreneurship lost its founder and most respected thinker and many of us lost a dear and kind friend. He is sorely missed but his legacy will endure forever. This article is his last completed work.

Definitions

At its simplest, social innovation represents new ideas that address unmet social needs (Mulgan et al., 2007). However, beyond this, there are two broad schools of thought concerning the definition of social innovation: new social processes and new social outcomes. The first emphasizes changes in social relations and often has a focus on rebalancing power disparities in society. For example, Mumford (2002: p. 253) noted:

> Social innovation…refers to the generation and implementation of new ideas about how people should organize interpersonal activities, or social interactions, to meet one or more common goals.

Westley and Antadze (2010: p. 2) subsequently expanded upon this.

> Social innovation is a complex process of introducing new products, processes or programs that profoundly change the basic routines, resource and authority flows, or beliefs of the social system in which the innovation occurs. Such successful social innovations have durability and broad impact.

Second, social innovation can be seen as the answer to social market failures in the provision of vital public goods. Phills et al. (2008: p. 36) proposed that social innovation is

> A novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals.

The Organisation for Economic Co-operation and Development (OECD) endorsed this definition but also acknowledged the process dimension of social innovation (2011: p. 1),

> Social innovation is distinct from economic innovation because it is not about introducing new types of production or exploiting new markets in itself but is about satisfying new needs not provided by the market (even if markets intervene later) or creating new, more satisfactory ways of insertion in terms of giving people a place and a role in production.

In addition to these two metadefinitions, three *types* of social innovation can be identified that cut across both (see **Table 1**). First, there is *incremental* innovation in existing goods and services to address social need more effectively or efficiently. Second, there is *institutional* innovation that aims to harness or reshape existing social and economic structures to generate new social value and outcomes. Finally, *disruptive* social innovation aims at systems change via political action and is typically driven by social movements aiming to reframe issues to the benefit of otherwise disenfranchised groups.

Social innovation can also be defined in terms of the level of its action or impact from the individual to the systems. Such levels can be mapped against the two main definitions of social innovation focused either on new processes or on new outcomes (see **Table 2**).

Finally, drawing upon theory from design thinking, Murray et al. (2010) set out the key stages of the development of a social innovation as a nonlinear process (see **Figure 1**). This model is characterized by a series of key inflection points where the development of an innovation moves first from prompts and proposals to prototyping (an important part of the design process), then to sustainability and, finally, to scale.

Table 1 Types of social innovation

Level	*Objective*	*Focus*	*Example organization (sector)*
Incremental	To address identified market failures more effectively: e.g., negative externalities and institutional voids	Products and services	Kickstart (low-cost irrigation foot pump) Aurolab (low-cost intraocular lenses) Afghan Institute of learning (female education)
Institutional	To reconfigure existing market structures and patterns to create new social value	Markets	Mpesa (mobile banking) Institute for one world health ('orphan' drugs) Cafedirect (Fair Trade)
Disruptive	To change the cognitive frames of reference around markets and issues to alter social systems and structures	Politics (social movements)	Greenpeace (environmental change) BRAC (micro-finance) Tostan (human rights)

Table 2 Levels of social impact

	Social process (example)	*Social outcome (example)*
Individual	Coproduction (Southwark Circle)	Lost-cost health care (Aravind Eye Hospital)
Organization	Wiki-production (Wikipedia)	Work integration social enterprise (Greyston Bakery)
Network/movement	Open source technology (Linux)	Nontraditional training and education (Barefoot College)
System	Microfinance (Grameen Bank)	Mobile banking (MPESA)

Contexts

Social innovation can be seen as a response to an acceleration of global crises and the so-called wicked problems characterized by multiple, contradictory analyses and diagnoses (Rayner, 2006; Murray et al., 2010). Examples include the failure of modern state welfare systems (Leadbeater, 1997; Mulgan, 2006a), the impacts of mass urbanization (Moulaert et al., 2007), the failure of conventional market capitalism, increasingly urgent global resource constraints, the impacts of climate change, increased social breakdown, rising life expectancy and associated health and social care costs, growing cultural diversity within and across countries, growing inequality, rising incidences of chronic long-term conditions and pandemics, behavioral problems associated with the 'challenge of affluence,' difficult transitions to adulthood, and endemic reductions in individual happiness and indices of well-being (Mulgan et al., 2007: p. 9). In this context, wicked problems can be seen as highlighting the failure of conventional solutions and established paradigms across all three conventional sectors of society: private sector market failures that ignore pernicious externalities or marginalized populations, public sector thinking in departmental silos, and an absence of focus on performance outcomes in civil society.

An important subset of these 'wicked problems' concerns public sector welfare reform in response to demographic and societal changes combined with the economic realities of rising welfare costs and worsening public finances. In a different reading of the rising interest in social innovation, such action is seen as a necessary (but not always automatic) companion to rapid technological change and economic innovation (Hamalainen and Heiskala, 2007). This conceptualization links to notions of social innovation as a process of reshaping of social relations to maximize productivity and economic development, often framed by the optimistic assumption that the benefits of these changes will be shared equally. Common to both contexts is a series of complex and multifaceted issues that drive innovation not only in processes and outcomes, but also, increasingly, as boundary-blurring activity across the conventional sectors of society. As Murray et al. (2010: p. 3) noted:

> Social innovation doesn't have fixed boundaries: it happens in all sectors, public, non-profit and private. Indeed, much of the most creative action is happening at the boundaries between sectors.

Indeed, social innovation can often be the product of trying to resolve apparent contradictions and tensions across different fields of action. Taken together, the three ideal-type sectors (public, private, and civil society) can be conceptualized as a triad represented in stability as a triangle. Between each of the three ideal-type points lies a range of hybrid organizations that combine elements of the ideal types in different proportions: these represent social innovation as boundary-blurring activities (see Figure 2). Examples include social enterprises that combine business logics and models with social objectives and ownership structures (such as mutual societies and cooperatives) and public–private partnerships that provide new models of welfare provision outside of, but often in tandem with, the state (Bovaird, 2006). Various models of the 'shadow state' exist in which community organizations, as well as larger charities and nongovernmental organizations (NGOs), function as a surrogate state in terms of the functions of an elected government (e.g., the Grameen organizations in Bangladesh that provide education, telecommunications, solar power, health care, employment, and financial services across the country).

The potential of social innovation across sector boundaries has also been demonstrated in practice by the emergence of social innovation 'hubs,' incubators, and networks such as the Social Innovation Exchange that aim to bring together disparate players from across institutional fields to spark new thinking and modeling (http://socialinnovationexchange.org). The value of clustering organizations working across boundaries in a larger innovation ecosystem is also behind the notion of 'Social Silicon Valleys' (Mulgan, 2006b).

Theoretical Traditions

The topic of innovation – like entrepreneurship – has been of interest to scholars for many years. Schumpeter's work in the first half of the twentieth century provided much of the foundational thinking for subsequent innovation research,

Figure 2 Social innovation: hybridity across boundaries.

particularly within an economic context. Of particular influence have been Schumpeter's (1942) reimagining of Marxian notions of 'creative destruction' caused by systemic innovation and his typology of 'five dimensions' of innovation. The latter provided a conceptual classification used in much of the subsequent analysis of innovation:

1. The introduction of a new product or an improved version of an existing product.
2. The introduction of an improved method of production.
3. The development of a new market (or entry into an existing market for a new player).
4. The development of a new source of supply or supply chain.
5. The more efficient or effective organization of any industry or sector.

Schumpeter's work was also significant in that it introduced the construct of the entrepreneur as endogenous to economic systems in contrast to conventional economic analyses that had largely cast the actor as an exogenous agent of change. Recently, Schumpeter's theory has been extended to include noneconomic forms of entrepreneurship and social entrepreneurship explicitly and broaden the categories of innovation. Even though Schumpeter's work transformed the study of innovation, it has also been problematic in that it has led to the rise of a 'heroic entrepreneur' focus of analysis that can obscure the critical operational role of collaborations, networks, and groups. (This has also been the case in social entrepreneurship research; see Nicholls (2010).)

The next significant contribution to innovation theory came from rural sociology and the analysis of the processes behind the diffusion of innovation in this context. (It is not entirely clear who first coined the term 'social innovation' to refer to novel solutions to social problems.) This research established categories of adopters of innovation – 'innovators, early adopters, early majority, late majority, and laggards' – that are still used today. Faced with a series of industrial crises, stagflation, and increasing overseas competition, a second wave of modern innovation research emerged from the 1970s onward focusing on the effects of new technologies on economic productivity.

In tandem with a range of new theorizing concerning the competitive strategy of firms, the 1980s saw the emergence of innovation studies based firmly within the management discipline and pioneered by von Hippel (1988). This work led to important subsequent contributions by Christensen (1997, 2002) and Chesbrough (2003). In the past 10 years, there has been a plethora of more generalist management books on aspects of innovation, as well as specific studies looking at a single aspect of innovation and its effects.

As part of this proliferation of work on innovation, a specific social innovation literature began to emerge, most notably with attempts by Drucker (1987) and Moss Kanter (1999) to blend commercial and social innovation theory together within a hybrid construct of 'business in society.' (Moss Kanter (1999) developed a model of corporate social innovation that suggested that cross-sector partnerships between not-for-profits and business offered valuable opportunities for innovation as a setting for 'beta testing' new ideas and processes. These pioneering ideas around 'new paradigm partnerships' led directly to subsequent work in 'corporate social entrepreneurship' (see also Collins's (2005) reflections on the similarities between his analysis of 'great' businesses and successful social sector organizations).) However, the distinctiveness of – as well as overlaps between – these two streams of work has been the subject of specific work only in the past 10 or so years. Building upon the analysis of the existing social innovation literature set out by Pol and Ville (2008), two broad conceptualizations of social innovation are identified here: innovation in social relations (that typically reflects process changes) and innovation to address social market failures (that typically reflects outcome changes). A third strand of social innovation theory, focused on macrolevel systems resilience, has also emerged from complexity theory.

Innovation in Social Relations

The largest and most well-developed body of work in this category specifically focuses on innovation that addresses various dimensions of changes in social relations. This literature can be subdivided into five categories of scholarship, as set out below:

- Research Design Challenges: Early work on social innovation developed from within behavioral science with a particular interest in devising 'social change' approaches to tackle key, contemporary social problems, often at a community level (Fairweather, 1967).
- Changes in Social Structures: Hamalainen and Heiskala (2007) argued that it is social innovation processes that ultimately determine the economic and social performance of nations, regions, and industrial sectors and organizations: "Social innovations are changes in the cultural, normative or regulative structures…of society which enhance its collective power resources and improve its economic and social performance" (2007: p. 59).
- Changes in Patterns of Work: Holt (1971) focused on social innovation within organizations, conceived of as new social patterns of employee interaction. This work was echoed in the activities of the Netherlands Centre for Social Innovation 30 years later (see Pot and Vaas, 2008).
- Diffusion of Social Change: from within sociology, there are analyses of the microlevel structures of innovation and diffusion that affect society – for example, how medical innovations spread across groups of clinicians – that have been classed as social innovation. Henderson (1993) was interested in the relationship between social innovation and political change in terms of diffusion processes. He explored how citizen movements catalyze social innovation – conceptualized as distinct from dominant cultural norms – from fluid positions outside of conventional societal structures.
- Urban Studies: There is a significant cluster of work within urban studies exploring innovative responses to social exclusion as social innovation under the heading of Integrated Area Development. Much of this work centers on innovation within social relations in urban contexts, and as a body of work, it explores the potential of public, private, and civil society models; interventions; and interactions. In Moulaert et al. (2007) characterized social innovation as

"a polymorphic constellation of counter-hegemonic movements and initiatives" (p. 196) engaged in active processes of social struggle and change.

Innovation to Address Social Market Failures

This stream of work relates to the outcome-driven model of social innovation already discussed above and focuses on innovation as the means by which new products and services can be provided to underserved market segments. At the macrolevel, this includes the mechanisms by which new markets are created in weak institutional spaces or to address market failures. The latter is conceived of as encompassing failures not only in commercial markets but also in public sector 'markets,' where the state fails to provide public goods, and civil society 'markets,' where charities, not-for-profits, and NGOs fail to provide effective goods and services to their beneficiaries. Such failures typically provide innovation opportunities, but can also provide challenges in terms of reconciling potentially competing institutional logics.

Resilience Theory

A third strand of social innovation theory has emerged recently focusing on its relationship with the overall sustainability and, particularly, the *resilience* of the larger ecosystem within which it evolves. The overall resilience of a system may be examined through the lens of the adaptive cycle, which is graphically represented by an infinity loop encompassing four phases: release, reorganization, exploitation, and conservation. The exploitation and conservation phases in the 'front' loop represent periods of growth and resource accumulation, where change is routine and almost always adaptive, while the release and reorganization phases in the 'back' loop can represent the introduction of novelty, either transformative (radical) or adaptive change, and renewal of the system. The back loop represents, therefore, a precarious moment from the point of view of whether the system remains stable, adapting, and learning but not transforming or whether it is pushed close to a threshold that tips the system into a new stability domain. The new domain may share characteristics with the old stability domain but will have radically different feedback loops, and hence different relationships between the phases (Moore and Westley, 2011). Resilience theory offers a systems-level model of the emergence and dissemination of patterns of social innovation.

Distinctive Challenges of Social Innovation

The structure of capitalism is often credited with providing a powerful incentive for the development and dissemination of commercially viable innovations. As long as markets are relatively open for innovators to sell what they believe people will be willing to pay for, there will be an incentive to innovate. With sufficient profitability, the innovators can attract the capital needed to expand, and other players have an incentive to copy or build on commercially successful innovations, contributing to their diffusion. This system has produced a powerful engine of innovation in capitalist economies.

While some social innovations may have significant commercial potential and benefit from this dynamic, many (if not most) create benefits for society that are not automatically rewarded in the marketplace (Phills et al., 2008). Direct beneficiaries may not be able or willing to pay more than the cost of the innovation, even when the social benefits would make up for such expenditure. And third-party payers may not have the resources (e.g., developing country governments), or may not even know the extent of social benefits created by a given social innovation, to judge how much to pay.

One example is education in developing countries. Innovative curricula and school designs might well improve outcomes in these countries, but without attendance by children in poor families, the improved education will not have its desired widespread social benefits. Attendance by children of the poor can be low for many reasons. For instance, with the rural poor, the parents might be just as happy with their children working on the small farm that constitutes the family's only source of income and food. One solution is paying poor families to send their children to school, tying payment amounts and timing to absentee rates, grade completion, graduation, and even enrollment in tertiary education programs. Yet, some countries can barely afford their education systems now, expecting parents to pay for textbooks, uniforms, and some school fees. The idea that social innovators working in this space can make sufficiently high profits to draw in competitors and create a vibrant market with rapid diffusion seems unlikely, no matter how effective the innovation is at improving educational outcomes. Similar dynamics exist in health care, sanitation, clean water, clean air, and so on. Social, long-term, and intangible benefits are hard to sell to individuals, especially those feeling the day-to-day pressures of poverty. Third parties, such as governments, multilateral agencies, major NGOs, and foundations, can help, but have limits and may not be a viable long-term sustainable source of revenue and profitability for a particular innovation.

Inception

Motivation does not seem to be a major problem. People innovate for many reasons. Research on innovators in business illustrates a wide range of motivations, some of which have nothing to do with making money. There are a variety of motivations for innovation, of which money is only one. It is conceivable that innovators who are driven to solve a social problem (or by other nonpecuniary motivations) will leave the economic dimensions of their innovations as an afterthought. They may be more concerned with developing something that achieves the desired social impact than with something that is economically sustainable and scalable. There are certainly many examples of social innovations that lack sustainable and scalable business models. This is a challenge when business model innovation may be what is needed to create a viable solution. The following are the key questions. Is there more of a disconnect between the innovation and finding a viable business model when the motivation of the innovator is social impact rather than making money? Are there advantages to blending these motivations?

Evaluation

In the case of commercial innovations, the market is the ultimate judge. With social innovation, an extra step is required to decide if the intended social impact is achieved and not offset by other unintended and undesirable side effects. This kind of standard is applied to some commercial products where public safety is an issue (such as pharmaceuticals), but it is crucial for social innovations since market success may not be at all correlated with the social impact of the innovation. Effective evaluation of performance impact is a challenge for social organizations: it can be costly and difficult. Moreover, there are, as yet, no commonly agreed methods or standards of evaluation for social impact, although this is changing with the growing recognition of the importance of this topic by funders. This raises a series of key questions:

- What needs to be measured to establish impact?
- Why should such an evaluation be conducted? Who should pay for it?
- For whom is the data intended? Who decides what counts as a legitimate social impact? In many cases, social innovators may have uncontroversial benefits in mind related to improving education, health status, increasing income opportunities for the poor, and so on. However, some goals are more controversial, such as women's rights, reproductive health decisions, political or ethical content in educational curricula, and more.
- Who should generate/collect the data? How participative should the data collection process be? Does it need to be done by a third party for objectivity?
- When should impact be evaluated?
- How should performance impact best be captured?

Considering each of these questions in turn may allow the most effective and appropriate methodology for a given social innovation to be discerned but will also typically raise difficult issues, not least potential contradictions across different perspectives on the nature and scale of an impact or benefit.

Diffusion and Scaling Impact

Social innovations, even those with demonstrated positive impact, have a reputation for scaling slowly, despite some clear exceptions, such as microcredit. Innovations require change, which commonly meets resistance, and without powerful financial incentives to counter the resistance or clear demand by consumers, it is not surprising that the pace of innovation and its spread will be comparatively slow. It may also be slowed by the fact that in some cases its spread depends on adoption by large bureaucratic institutions such as governments. Consider the example of controlling scurvy in the British Navy that Rogers mentions early in his classic *Diffusion of Innovations*. In this case, even with a compelling controlled trial as early as 1601 showing how lemon juice can prevent scurvy and save many sailors' lives, and another study in 1751, it took until 1795 before the British Navy adopted the innovation as policy and until 1865 before the British Board of Trade adopted the innovation. Commercial innovations can also diffuse slowly. However, at least on the commercial side, if you can demonstrate value to paying customers, and a profitable business model, there are incentives for the innovation to be spread more quickly, especially if it is not fully protected intellectual property. Copycats, clones, and adaptations are likely to arise as others see an opportunity to profit. In the absence of a profitable, self-funding business model, many social innovations struggle to attract the capital and operating funding for expansion. Consider a clinic that provides and monitors tuberculosis treatment that can sustain itself on government funding once that funding is in hand, but it receives funding only months after opening each new site, requiring philanthropic operating capital to start up each new site. The government funding is not enough to repay a loan. Funding is not the only barrier. Some social innovators also report difficulty finding and retaining the necessary talent to scale their innovations, due to the distinctive skills required (often a mix of business skills and technical expertise in the field in which they are operating) and due to limits on compensation because of limited profitability and norms against profiteering from the poor. High salaries in social ventures that get their revenue from governments, aid agencies, or from the poor themselves are frowned upon.

Innovation Ecosystems

Recent literature on innovation has recognized that successful innovations of all kinds require an ecosystem of resource providers, value chain partners, and complementary players. This poses special challenges for social innovators because they are often operating in situations (distressed environments) in which the surrounding ecosystems are weak. Supply chains and distribution networks may be unreliable and underresourced. Infrastructure may be flawed or nonexistent. Institutions that are taken for granted in well-developed markets are often absent or weak. Sometimes social innovators have to fill institutional voids. They cannot count on the profit incentive to induce others to fill the gaps. Institutional voids affect commercial entrepreneurs as well. They are more prominent in social innovation because the spaces in which social entrepreneurs frequently choose to work have weak institutional, economic, and social ecosystems, and because social entrepreneurship is a relatively recent phenomenon with distinct resource and capability needs that have not been well served by existing markets.

Altogether, social innovations face some distinctive challenges in that they are not incentivized or reinforced by the kind of market system that rewards and supports the development of profitable commercial innovations. This raises serious research questions regarding how societies can create the institutional environment to optimize the benefits of social innovation. However, there are promising developments. One example is Social Impact Bonds (SIBs), which represent an interesting example of how incentives can be aligned across disparate groups engaged in social innovation. SIBs use outcome-based payments linked to rigorous performance metrics to align the interests of external investors, government departments (or charitable foundations), and service providers around optimizing interventions that address difficult social issues where success leads to significant social impact.

Failure, and Unintended Consequences

All innovation is risky, and many are bound to fail. If societies want to promote social innovation, they have to tolerate and learn from failure. Yet, there appears to be a norm of hiding failure in the social sector. There seems to be a sense of shame at failing to deliver intended social benefits. The innovator has let down society or a set of needy beneficiaries, and perhaps a generous donor or an investor intent on achieving that social impact. To complicate matters, some failures are unknown because of lack of serious evaluations. This has caused errors to be repeated and progress to be slowed.

Moreover, it should also be acknowledged that social innovation is not, in and of itself, always a positive thing. Indeed, social innovation may have a 'dark side.' This could be evidenced in several ways, for example:

- By socially divisive or destructive objectives and intentions (e.g., secret societies or extreme political parties).
- By unintended consequences that achieve negative social effects (e.g., by excluding some groups from the focus of social goods, services, or change).
- In cases of operational failure, mission drift, or strategic co-option by an external party.

Conclusion

Today, social innovation may offer vital solutions to key global problems such as climate change, the crisis of the welfare state, health pandemics and failures, social dislocation and inequality, and educational failure. Indeed, rather than conceptualizing social innovation as a subset of technological–economic innovation, it may be the case that the reverse is now true.

Social innovation offers a compelling set of examples of hybrid logics and organizational models that offer both microlevel novelty and the potential for macrolevel systems change influence. These models provide useful templates to understand how innovation and change can be operationalized in other settings, as well as generating a range of interesting research questions concerning how to go to scale and the development of ecosystems models of social and environmental change. Indeed, policy makers, private sector leaders, and civil society actors are increasingly recognizing the need for more fluidity across the ideal-type sectors of the Triad model shown above.

However, the study of social innovation remains at an early stage of development. There are many important research topics that require further work including the measurement of innovation outcomes and impacts; the governance and accountability mechanisms for organizations in change processes or systems in flux; the challenges of the 'liability of newness' in terms of societal legitimacy, funding mechanisms, and wider resource strategies for social innovation; and the political processes around successful social innovation. Both in terms of practice and research, social innovation offers rich opportunities for future action.

Social Insurance: Legal Aspects

Gerhard Igl, Christian Albrechts University, Kiel, Germany

Abstract

To reach the goals of social security, the technique of social insurance has been one of the most important tools in the evolution of welfare states. Social insurance, in the sense of Bismarck's social insurance, has undergone major changes. The initial role of social insurance, the social protection of workers, has lost its importance as the personal scope of social insurance has widened. Other forms of social protection, especially state-financed social programs for families, unemployed people, or persons in need, are increasingly prevalent.

Insurance is considered a way of protecting against the consequences of negative future events (risks or contingencies) in a collective manner with a special technique of financing. Social insurance is a kind of insurance organized by public authorities on the basis of legislation, and it is usually compulsory. Its goals include coverage against the consequences of risks like sickness, industrial accident, invalidity, old age, and unemployment for a large part of the population of a nation. To attain these goals, a degree of compulsion is recognized to be necessary. One of the main criteria for distinguishing between social and private insurance is the way of calculating and financing the risk. In the field of social insurance, the risk ceases to be the fundamental criterion since social aims prevail over the economic criteria governing private insurance. Social insurance effects income redistribution, usually described as redistribution between healthy and sick, richer and poorer, younger and older people, or households without and with family members. In other words, social insurance creates a bond of solidarity beyond a mere solidarity of sharing individual risks. The prototype of social insurance was Bismarck's social insurance in Germany (with passage of the Health Insurance Act of 1883). This technique of social protection became widespread and is still considered one of the most important forms of social protection. Because the financial basis of social insurance schemes is earnings related, this technique of social protection will have to change in countries where the role of earnings from work is diminishing.

Social Insurance and Private Insurance

Insurance is a way of providing for the consequences of negative future events (risks or contingencies) in a collective manner with a special technique of financing. Besides the different ways of calculating and financing the risks, social insurance is organized by public authorities through legislation, and is usually compulsory, while private insurance is offered by private enterprises and is usually voluntary. Social insurance seeks to provide coverage against the consequences of risks for a large part of the population of a nation. To attain these goals, a compulsory form of insurance is considered a necessity. Bismarck's social insurance in Germany is in some ways the prototype of social insurance. However, his social insurance covered only workers rather than the general population (Koehler and Zacher, 1982; Peters, 1993).

The differences between social and private insurance can be found in their goals, their techniques of protection, the legal form of their insurance bodies as private or public organizations, and their way of financing the benefits. But there is no clear distinction between them. Sometimes, the goals of social insurance are attained by compulsory private insurance and, in some countries, the bodies responsible for social insurance are private bodies.

In the field of private insurance, the basis of calculation of the premiums is the risk. In the field of social insurance, the risk is less important, and social aims (such as health and welfare) prevail against the economic criteria.

Private insurance, moreover, distributes the burden of an individual risk across a group. Social insurance has the same effects, but it also effects income redistribution between those who are healthy and sick, richer and poorer, younger and older people, or households without and with family members.

Two Characteristic Items of Social Insurance: Financing and Organization

Thus, two characteristic items of social insurance remain, which allow us to distinguish between social insurance and other techniques of social protection. Those interlinked items are the ways of financing social insurance and the organization of social insurance.

Financing

Social insurance benefits were originally financed by contributions levied on earnings and divided between employee and employer, thus expressing the shared responsibility between employer and employee with regard to work-related social risks. State subsidies completed the financing. However, this scheme changed over time. Some countries introduced increasing state subsidies, while others changed the proportion of the contributions burden payable by employer and employee. In Germany, for example, the employees had to relinquish a public holiday to compensate employers for the new financial burden created by the introduction of long-term care insurance. Currently, there are ongoing discussions about changing the financial basis from the earnings of employees to the surplus value of enterprises.

Organization

Originally, social insurance bodies were special bodies that were not directly integrated in the administrative organization of a state. Sometimes, they are coadministered by representatives of employers and employees. This kind of self-government is more prevalent in countries where social insurance bodies are private organizations. In countries with special public authorities for social insurance, but without self-governing or autonomous elements of administration, the ideal image of social insurance is left behind.

Social Insurance and Social Security

The concept of social insurance should not be confused with the concept of social security (cf. UN Declaration of Human Rights, Art. 22), which is an international goal of social policy. Social insurance is considered a special, albeit widespread technique of social protection.

From the perspective of international law, social insurance does not entail special legal problems. Nevertheless, international law scholars have taken a special interest in social insurance as a mechanism of social protection. Thus, many international treaties and other international or regional instruments, especially those involving Europe, address social insurance.

In the field of social security, international law has two main dimensions: (1) coordinating different national social security schemes to guarantee freedom of movement, and (2) defining social standards and aims (e.g., minimum standards, standards to attain, and principles).

The coordination task was originally primarily due to the migration of workers, while the standard defining task began with the Treaty of Versailles, which can be considered the basis of the development of an international social policy (Zacher, 1976).

Fulfillment of International Requirements (International Standards of Social Insurance)

Two kinds of requirements prevail internationally: attainment of minimum standards and achievement of higher levels than a given minimum.

Minimum Standards

The best-known and most basic international instrument to set minimum standards of social security is Convention 102 of the International Labor Organization (ILO) (1952). This convention, ratified by 47 countries, contains minimum standards regarding medical care and benefits in the case of sickness, unemployment, old age, employment injury, maternity, and invalidity, and for survivors. This convention applies to insurance schemes as well as other schemes of protection.

Higher Levels of Social Standards

The European Social Charter (1961) and the Revised European Social Charter (1991) of the Council of Europe, a regional instrument for the European countries, serve as a social standard instrument for the European Union nations. In the frame of the Council of Europe, other social security conventions (e.g., the Code of Social Security) also aim at higher social standards (Becker et al., 2010; Pieters, 1999a).

Social Insurance Benefits

Range of Benefits

The range of risks covered by social insurance schemes, labeled as 'traditional' social risks or contingencies, is described in ILO Convention 102 on minimal standards of social security (see section Minimum Standards). As new social risks develop, it is not clear whether protection will be provided by social insurance schemes or by other means (van Langendonck, 1997; Pieters, 1998).

Social insurance bodies do not provide benefits unique to social insurance. Other bodies of social protection and even private insurance bodies provide comparable or identical benefits. However, there are typical links between social insurance and the benefit provided, especially for those cash benefits designed to replace former earnings (e.g., sickness benefits or old-age pensions). As the insured person pays contributions based on his or her earnings (usually a certain percentage of the income), the benefit replacing the earnings is calculated as a function of the former earnings and is not provided as a flat-rate sum.

Whereas private insurance is almost always paid in cash, social insurance benefits can be either in kind or in cash.

Guarantee of Benefits

In some countries, entitlement and even qualifying periods for social insurance entitlement are protected by the constitution. In the German constitutional doctrine, contributions to the old-age pension scheme are protected by the constitution as property.

Public–Private Mix of Benefits

Initially, social insurance benefits were the only way of providing a subsistence base in the case of risk occurrence. Nowadays, social insurance benefits are increasingly complemented by other means of protection. Mainly in the field of old-age pensions, the interplay of public, occupational, and private protection increasingly serves as a current mode of protection (International Bank for Reconstruction and Development, 1994).

Future Developments in the Field of Social Insurance

To reach the goals of social security, the technique of social insurance was one of the most important tools in the evolution of welfare states. Social insurance, in the sense of Bismarck's social insurance, has undergone major changes. The initial role of social insurance, the social protection of workers, has lost its importance as the personal scope of social insurance has widened. Other forms of social protection, especially state-financed social programs for families, unemployed people, or persons in need, are increasingly prevalent.

Today, there is no unique mode of using social insurance to address social problems. Social insurance schemes rely mainly on financing by contributions and are thus, as regards their financing basis, dependent on the evolution of earnings. This reliance is considered a critical factor in the future financial stability of social insurance schemes and is broadly under discussion (Pieters, 1999b, 2003; van Langendonck, 1997; Berghman, 2002; Brooks and Assaf, 2005).

This article is a revision of the previous edition article by L.F. Berkman, volume 21, pp. 14327–14332, © 2001, Elsevier Ltd.

Abstract

Social relationships have long been linked to health outcomes. To understand this association various disciplines have approached the empirical understanding of this association from different theoretical and methodological approaches. This article will summarize the historical background of these approaches, the evidence linking social networks to mortality, the theoretical models that explain how this might occur, review the behavioral, psychological, and biological pathways by which social networks influence health, and conclude by providing recommendations on how these may be applied to future research and interventions.

There is now substantial evidence that being socially connected to others not only is relevant to mental health and emotional well-being, but also has a powerful influence on physical health and longevity. Research evidence indicates that having fewer and poorer social relationships is associated with poorer physical health and greater risk for early mortality, while having more and better relationships is associated with better physical health and greater odds of survival. The influence of social relationships on physical health has been examined across a number of different disciplines including psychology, medicine, epidemiology, sociology, anthropology, and public health, from which diverse conceptualizations and measurement approaches have emerged. From this interdisciplinary perspective, multiple pathways have been identified by which social relationships may influence physical health outcomes.

The aims of this article are to (1) review the historical and theoretical perspectives that guide research across diverse disciplines; (2) define the multiple ways in which social relationships have been systematically studied; (3) review the findings that link social relationships to mortality; and (4) provide an integrative guide for future interdisciplinary research and interventions in this field.

Historical and Theoretical Conceptualizations

Across history multiple disciplines have proposed theories that have provided the foundation for empirical investigations of the association between social relationships and health. These include writings from the sociologist Emile Durkheim (1897), psychiatrist John Bowlby, anthropologists Elizabeth Bott and Clyde Mitchell, epidemiologist John Cassel (1976), and psychiatrist Sidney Cobb (1976). These writings give us insight about social integration, social networks, and social support. Each of these is a concept that describes the structure, functions, and processes of social relationships.

One of the earliest historical contributions to the understanding of social relationships and health comes from the renowned French sociologist and philosopher Emile Durkheim (1897/translation 1951). He examined suicide rates across social classes, cultures, religious affiliation, and gender, highlighting the importance of social environment and integration. More specifically, he identified different types of suicide: egoistic, altruistic, anomic, and fatalistic suicide. Egoistic suicide is a result of excessive individualism and detachment from society. Lack of connection to society is thought to be a lack of connection to life, as being a part of society gives meaning in life. Thus, low social integration with society results in low value on human existence and is associated with more egoistic suicide, and high social integration with society results in high value for human existence and is associated with low egoistic suicide.

In 1969, John Bowlby introduced the concept of attachment theory which proposes that it is a universal biological need to connect socially or create social bonds (Bowlby, 1969). Bowlby's theory was influenced by the work of the Nobel Prize winner Konrad Lorenz (1935) who showed that attachment or imprinting (among ducklings) was an innate tendency that increased the odds of survival. Bowlby similarly argued that among humans there is an innate tendency to form a secure attachment to a primary attachment figure (usually mother). This attachment allows for a secure base from which an infant or a toddler can explore; however, threats to proximity to the attachment figure would illicit fear and insecurity. Proximity-seeking behaviors such as crying or smiling are thought to represent evolutionarily adaptive behaviors, as those infants that could maintain proximity to their mother would be more likely to survive and produce offspring of their own. Thus, Bowlby suggests that fear and insecurity around strangers is an innate survival mechanism. Further, Bowlby contends that the reliability and security of the primary attachment figure provides the basis for forming loving, trusting, secure relationships in adulthood. This innate tendency to form attachments to others is thought to be adaptive for survival.

Social Network Theory

The early 1950s gave rise to the consideration of the social network. The term 'social network' has been attributed to sociologist Barnes (1954) as well as the anthropologists Bott (1957) and Mitchell (1969), from whom came some of the first fieldwork done on social networks. Social network theory describes the individual as a node and the relationship to others within the network as ties. A social network then can be illustrated as a network of ties connected by individuals or nodes. This perspective is inherently relational. Social network theory has been applied across many disciplines to examine the

relationships among individuals, family, groups, and even society. According to the social network perspective, there is less importance put on the characteristics of the individual, but rather it is the relationship of ties within the network that is important. Networks are thought to have an influencing pressure on individuals' attitudes and behaviors, which in turn may influence health, and social network analyses are a systematic way of detecting the magnitude of these pressures. Although, epidemiology has used the term 'social network,' it rarely uses social network analysis, the systematic process of mapping the interconnections among people. Social networks have been examined not only from the perspective of epidemiological studies, but also to model health education, disease prevention, spread, and treatment, as well as health-care structure and coordination in an effort to understand the association between social networks and health.

Social Support

In 1976, two influential articles were published that emphasized the health relevance of the qualitative aspects of social networks that gave rise to an emphasis in health psychology on the functional support that social networks may provide. Cobb (1976) defined social support as information from others that one is cared for, loved, esteemed, and part of a mutually supportive network. In his article, he presented evidence suggesting that these social support resources were important in dealing with stressful life events such as pregnancy, hospitalization, and bereavement. Cassel (1976) focused more on the biological processes linking support to health. He argued that social support might best be seen as a protective factor and reviewed studies suggesting that such a relationship factor may modify bodily processes (e.g., blood pressure, endocrine activity) in health-relevant ways. These two reviews highlighted the important role that social support might play on physical health outcomes.

Conceptual Models Linking Social Networks to Health

Since about the 1970s there has been more systematic interest in the health influence of social networks and the social support they provide. In particular, these studies seemed to make competing predictions. Some argued that social relationships were primarily protective under stressful conditions by providing resources (informational, emotional, tangible) that buffer the deleterious effects of acute and chronic stress (stress buffering model). Others contend that social relationships may be associated with protective health effects through more direct means, such as cognitive, emotional, behavioral, and biological influences, that are irrespective of levels of stress (main effects model). Cohen and Wills (1985) reviewed the studies conducted to that point in an effort to test these seemingly competing hypotheses. They concluded that study's characteristics determined when each model was most predictive. Studies that measured the functional aspects of social support supported the buffering model, while studies that measured social integration supported the main effects model. However, subsequent articles suggested that functional measures may also show a direct effect (Uchino, 2004). Thus, functional support may have both stress-related and a direct effect on health outcomes but this may occur via different pathways. As such, the main effects and buffering models are not necessarily competing perspectives but highlight different contexts and processes by which social support operates (Uchino, 2004). Where they converge is in the more 'downstream' processes, such as health behaviors, that ultimately link them to health.

Stress-Related Models

The stress buffering model focused on the possibility that support from social network ties might decrease exposure to negative life events (Gore, 1981). This model suggests that social support is beneficial because network members may provide us with the resources to avoid or reduce exposure to stressors. There are multiple pathways by which social support may reduce stress exposure. First, social support may intervene between stress exposure and stress appraisal to prevent the appraisal of stress (Cohen and Wills, 1985). Second, social support (e.g., informational support) can help individuals make informed decisions that minimize their subsequent stress exposure via proactive coping (Aspinwall and Taylor, 1997). Finally, adequate social support may help decrease exposure to 'secondary stressors' (Pearlin, 1989). For instance, stress at work may, in turn, increase the likelihood of conflict at home. However, if spousal support reduces the stress of work, it may effectively eliminate potential spillover into marital interactions and reduce exposure to such secondary stressors.

The most well-known stress-related model is the buffering model of support (Barrera, 2000; Cohen and Wills, 1985). This model differs from the stress prevention model in that individuals might still experience stress, but social support is predicted to decrease the strength of the association between stress and physical health outcomes (Cohen and Herbert, 1996). This model is based on the possibility that stressors have adverse influence on health behaviors and physical health outcomes but that appropriate support can be an important resource in helping minimize such links. Cohen (1988) has postulated that this stress buffering occurs through a cognitive appraisal process that can, in turn, reduce the normally robust association between stress and health-related outcomes.

A major variant of the stress buffering model is what has been called the matching hypothesis (Cutrona and Russell, 1990). The matching hypothesis predicts that stress buffering is most effective when the type of support matches the needs or challenges of the stressful event. More specifically, it predicts that informational and tangible support should be most effective for controllable events (e.g., preparing for a job interview), whereas emotional and belonging support should be most effective for uncontrollable events (e.g., job layoff; Cutrona and Russell, 1990). This is one of the few theoretical models that highlights how different functional components of support might be related to outcomes based on the stressor context.

Direct Effect Model

The direct effect model postulates that social support is effective more generally regardless of stress levels (Cohen and Wills, 1985). The article by Cohen and Wills found that structural measures of social relationships were more likely to demonstrate direct effects. The direct effect of structural measures was thought to represent its influence on social identity through

direct or indirect social control processes (Thoits, 1983; Umberson, 1987). Direct social control may be seen in pressure to behave more healthily (e.g., get more sleep, eat better, exercise more, see a doctor) from others. Indirect social control can be evidenced by individual engaging in healthier behaviors and avoiding riskier behaviors because relationships provide greater meaning in life. However, there is now evidence that functional support can also have direct effects on outcomes by promoting a sense of connection, self-esteem, and control over life due to knowing that you are cared for and supported by others (Lakey and Orehek, 2011; Thoits, 2011; Uchino, 2004).

Recently, Lakey and Orehek (2011) have proposed relational regulation theory (RRT) to account for direct effects of social support on mental health outcomes. According to RRT, everyday interactions (e.g., talking about events of a typical day, gossip, sports talk) regulate an individual on a daily basis, which may result in positive outcomes like general comfort with that person and a sense of well-being (Lakey and Orehek, 2011). These daily interactions can also serve as the basis for stress buffering or prevention links as individuals generalize their relationship representations to stressful context (i.e., is this a person whom I am comfortable with likely to be supportive during stress?).

Assessment of Social Networks

Social networks, social integration, and social support are often used interchangeably but conceptually represent different approaches to understanding the influence of social relationships on health and longevity. Given the diverse ways in which social relationships may be conceptualized it is not surprising that their influence has been measured in similarly diverse ways. Three major components of social relationships are consistently evaluated: (1) the degree of integration in social networks, (2) the social interactions that are intended to be supportive (i.e., received social support), and (3) the beliefs and perceptions of support availability held by the individual (i.e., perceived social support). The first subconstruct represents the structural aspects of social relationships, and the latter two represent the functional aspects. Notably, these different subconstructs are only moderately intercorrelated, typically ranging between $r = 0.20$ and 0.30. While each of these conceptualizations has been significantly associated with morbidity and mortality, it is thought that each may influence health in different ways. Epidemiological studies that have linked social relationships to mortality can be broadly broken down further into the measurement approaches described in **Table 1**.

Mortality Data on Social Networks, Integration, and Support

There is now substantial evidence for the protective effect of social relationships on risk for mortality from all causes. Some of the first epidemiological evidence was highlighted in the article by House et al. (1988). They summarized data from five prospective studies, including the Alameda County (Berkman and Syme, 1979), Evans County, Tecumseh, Eastern Finland, and Gothenburg studies. Each of these studies was designed to examine large community samples of initially healthy individuals. They assessed their involvement with social relationships, and then followed them over several years to determine whether the level of social integration predicted who would still be alive at the follow-up. Indeed, evidence indicated that those less socially integrated had significantly higher age-adjusted mortality risk relative to those more socially integrated.

Since then, the number of studies examining the effect of social connections (see further description below) on mortality has grown exponentially. In a meta-analysis of 148 independent prospective studies, with data from 308 849 individuals, followed for an average of 7.5 years, results indicate that individuals with greater social connections have a 50% increased

Table 1 Measurement approaches used to assess social relationships

Type of measure		*Description*
Functional		*Functions provided or perceived to be available by social relationships*
	Received support	Self-reported receipt of emotional, informational, tangible, or belonging support
	Perceptions of social support	Perception of availability of emotional, informational, tangible, or belonging support if needed
	Perception of loneliness	Feelings of isolation, disconnectedness, and not belonging
Structural		*The existence and interconnections among differing social ties and roles*
	Marital status	Married vs other
	Social networks	Network density or size, number of social contacts
	Social integration	Participation in a broad range of social relationships; including active engagement in a variety of social activities or relationships, and a sense of communality and identification with one's social roles
	Complex measures of social integration	A single measure that assesses multiple components of social integration such as marital status, network size, and network participation
	Living alone	Living alone vs living with others
	Social isolation	Pervasive lack of social contact or communication, participation in social activities, or confidant
Combined		*Assessment of both structural and functional measures*
	Multifaceted measurement	Multiple measures obtained that assess more than one of the above conceptualizations

odds of survival compared to those who were less socially connected (Holt-Lunstad et al., 2010). The effect was consistent across gender, age, initial health status, and causes of mortality. Importantly, controlling for initial health status helps clarify the direction of the association. Most of the studies were population-based and thus examined initially healthy participants. However, even among those who were ill, greater social connectedness was associated with greater odds of survival. Thus, regardless of initial health status, those who were more socially connected lived longer. Most notably, the overall magnitude of the effect of social connections on risk for mortality was comparable with and in many cases exceeds the effect of many well-established risk factors for mortality (**Figure 1**). For instance, lacking social connectedness carries a risk comparable to smoking up to 15 cigarettes per day, and is greater than alcohol abuse, physical inactivity (sedentary lifestyle), obesity, and air pollution, among others.

The magnitude of risk reduction differed significantly across the type of measurement approach examined. While both structural (Odds Ratio, OR = 1.57) and functional measures (OR = 1.46) were significantly associated with greater odds of survival, living alone (OR = 1.19) and received support (OR = 1.21) were poor predictors of survival. Notably, studies that utilized complex measures of social integration were the best predictors (OR = 1.91). Thus, assessments that took into account the multidimensional aspects of social relationships were associated with a 91% increased odds of survival. Such complex measures of social integration may also be stronger predictors because they are more stable over time than perceptions of support.

There is also reason to believe that the overall effect of social connections on mortality may be a conservative estimate. Most studies made adjustments for initial health and other lifestyle risk factors to establish the independent influence of social connections on risk for mortality. However, social relationships are inextricably linked with multiple pathways associated with mortality. For example, excessive alcohol consumption is associated with poor social support (Peirce et al., 1996; Steptoe et al., 1996); moreover, individuals with positive social relationships engage in less risky health behaviors (Jessor et al., 1998) This includes smoking cessation (Mermelstein et al., 1986), seat belt use, adequate sleep (Brummett et al., 2006), healthy diet (Fuemmeler et al., 2006), regular exercise (Okun et al., 2003), dental hygiene, etc. Therefore, these analyses eliminate one of the pathways by which social relationships may influence risk for mortality. The overall effect may also represent a conservative estimate because most studies failed to measure relationship quality. Thus, estimates likely include both high- and poor-quality relationships. Given that negativity in relationships has been associated with an increased risk for early mortality (Friedman et al., 1995; Tucker et al., 1996), this would suggest that quality does matter. Failure to account for negative or detrimental social relationships within the broad measures utilized across studies may have reduced the overall effect and the effect of positive social relationships on mortality may actually be much larger.

Figure 1 Comparison of odds (lnOR) of decreased mortality across several conditions associated with mortality. Note: Effect size of zero indicates no effect. The effect sizes were estimated from meta analyses; A = Shavelle et al., 2008; B = Critchley and Capewell, 2003; C = Holman et al., 1996; D = Fine et al., 1994; E = Taylor et al., 2004; F,G = Katzmarzyk et al., 2003; H = Insua et al., 1994; I = Schwartz, 1994. CHD, coronary heart disease; BMI, body mass index. Source: Holt-Lunstad J., Smith T.B., Layton J.B., 2010. Social relationships and mortality risk: a meta-analytic review. Pathways by which Social Relationships May Influence Health

Social relationships can have either direct effects on physiology (e.g., cardiovascular, neuroendocrine, immune functioning) or indirect effects through lifestyle or behavioral effects.

Social Support

Social networks may have a significant influence on health via the provision of various forms of support. Types of support have been categorized into subtypes including informational, emotional, and tangible or instrumental support (Schaefer et al., 1981). Informational support refers to the information or advice that is provided by network members. This may be directly relevant to one's health such as giving recommendations on lifestyle, behavioral, or medical choices; however, it may also be indirectly related to health. For instance, advice or guidance relevant to major life decisions or how to handle a stressful situation may help buffer the subsequence stress response. Emotional support is the love, understanding, and compassion shown by network members. Feeling cared for and validated can influence not only one's appraisal of a potentially stressful situation but also a sense of meaning and purpose in life that, in turn, can influence self-care and less risk taking. Because emotional support is more intimate it is often provided by closer relationships, although other relationships may provide emotional support in circumscribed situations. Instrumental, or often referred to as tangible, support is the help, aid, favor, and direct assistance that others provide. This can include a ride to the doctor, getting groceries, cooking meals, providing money, or caring for children.

Social Influence

Social norms can also provide a powerful influence on health. Although some norms may vary across cultures or social groups, there are often very powerful norms on the acceptability of certain behaviors and violations of these norms are enforced socially via social disapproval and rejection. For instance, many unhealthy or risky behaviors are associated with social disapproval (e.g., smoking, substance abuse, risky sexual practices) while many healthy behaviors are socially approved of (e.g., being physically active, maintaining a healthy weight) and may be associated with reward or praise to reinforce such behaviors. It is important to acknowledge, however, that one's social network can have a detrimental influence as well. For instance, there is some evidence that when a social network is filled with members exhibiting negative health behaviors then there may be social contagion to conform to these unhealthy social norms (e.g., smoking, obesity; Christakis and Fowler, 2013).

Social Participation and Engagement

Another important way in which social networks may influence health is via involvement in that network. Social participation includes activities such as getting together with friends, volunteering, church attendance, belonging to groups, involvement at a community level, and participating in sports, among others. It is through social engagement that social roles, norms, and capital are established and reinforced. Involvement in social groups and activities leads to the establishment of social roles that can provide a sense of meaning and purpose in life. Such engagement may also lead to obligation to others and provision of support, such that an individual becomes the source on whom others can depend on. It is perhaps the interdependence that leads to attachment to one's social group or community, first described by Durkheim, which influences mortality.

Person-to-Person Contact

Importantly, it must be acknowledged that having greater social contact can influence exposure and transmission of infectious diseases. Social network analysis has been utilized to track the transmission of such infectious disease and finds that it is not random but rather can move within social networks. However, it is remarkable that both epidemiological and experimental studies have found that a greater diversity of social relationships is actually associated with better immune functioning (Cohen, 2003).

Biological Pathways

Although social relationships are linked to psychological processes (e.g., stress and depression) that influence health outcomes in their own right (Rozanski et al., 1999); the influence of social relationships on long-term health cannot be completely explained by these processes. Most of the epidemiological evidence statistically controlled for these factors and found social relationships to exert an independent effect on risk for mortality. Reviews of such findings suggest that there are multiple biologic pathways involved (physiologic regulatory mechanisms, themselves intertwined) that, in turn, influence a number of disease endpoints (Uchino, 2006; Uchino et al., 2007; Uchino et al., 1999). The structure and functions of social networks have been linked to health-relevant physiological processes including cardiovascular, neuroendocrine, and immune processes (see reviews: Uchino, 2004; Uchino et al., 1996).

Conclusion

We have now established a robust association between social relationships and mortality. The future generation of research needs to consider both macro- and micro-level processes, and thus a multilevel interdisciplinary perspective is needed. From a macro-level perspective we need to consider cultural norms of relationships, marriage and cohabitation, familial obligation, intergenerational living, societal values, structures, and their respective implications for public health. Similarly, we need a further understanding of the micro-level relationship processes including relationship quality, relationship distress, interpersonal abuse, and interpersonal communication. Similarly, we need to consider the pathways by which such an association occurs at both macro- and micro-level processes. Macro-level processes including social engineering and wellness program participation, and micro-level processes including affect regulation and gene–environment interactions.

A new generation of research will also need to consider the role of technology in understanding social networks and interpersonal relationship functioning and the implications for

public health. Over the last decade or so, there has been a dramatic shift in the way in which people interact socially as a result of advancements in technology. Internet and mobile phone devices, and their associated services, have made it easier for people to communicate and connect with others than ever before. However, there is some evidence to suggest that despite these advances in technology, during this same time period people are reporting greater loneliness and social isolation (McPherson and Smith-Lovin, 2006). Thus, future research will need to consider both the potential benefits and deleterious effects of technology-mediated social networks and social interactions, and the implications for utilizing such technology in interventions.

Abstract

This article reviews and integrates research on social intelligence and competence. Firstly, the differences in the definitions of abilities, skills, intelligence, competence, individuals' potentials, and behavior are described. Secondly, theoretical models and measurement methods of social intelligence are contrasted, and requirements for social cognitive ability tasks are established. Thirdly, some representative conceptualizations of social competence are systematically compared and integrated into a framework of socially competent behavior that differentiates between the individual's potential and the resulting behavior. Finally, measurement issues of social skills and competence are discussed (e.g., accounting for situational variability and the question of adequate outcome criteria).

Introduction

During the last decades, new constructs (e.g., emotional and social intelligence, see Mayer et al., 2000; Weis and Süß, 2005 for overviews) in addition to the classical academic understanding of intelligence and personality have been considered capable of describing human attributes more comprehensively. Although still facing methodological problems, emotional intelligence attained the most prominent position (Lievens and Chan, 2010), while social intelligence with the longest history languishes in stagnation (Conzelmann et al., 2013; Landy, 2006; Weis and Süß, 2005). At the same time, social skills and competence received increased attention in applied disciplines such as personnel selection and development, clinical psychology (e.g., autism), and in school settings.

This article describes and integrates the various approaches to specify and assess social intelligence and competence. In the following sections, we deal with the terminology as applied in this article, the construct of social intelligence, and finally we describe and integrate conceptualizations of social competence into a framework of socially competent behavior.

Terminology

Imagine the following situation:

Paul, a team leader in a large corporation, has been asked by his superior, David, to hand in the annual team report earlier than expected. The report is in part the basis for salary increases. At the moment, one of his subordinates, Andrea, is faced with an ongoing divorce. He depends on her contribution to finish the report.

What are the resources Paul needs to accomplish the situation? Apart from abstract academic abilities (e.g., verbal reasoning or retrieval abilities), expert knowledge, and behavioral and cognitive skills (e.g., computer skills or writing skills), his social and emotional abilities and skills can be helpful to accomplish the situation:

1. Social cognitive abilities (e.g., interpret David's verbal and nonverbal behavior in terms of the severity of the situation; anticipate how Andrea will feel when he has to confront her with the problem).
2. Social knowledge (e.g., knowing possible action alternatives or how Paul himself can emotionally cope with the situation in order to function effectively).
3. Social behavioral and cognitive skills (e.g., communication skills such as sending the appropriate nonverbal cues when talking to Andrea, skills in self-regulation such as being capable of applying techniques to adapt to the situation).

All the above-mentioned concepts allow the assessment of individuals as more or less capable, more or less skilled, and so on. Apart from these cognitive and behavioral resources, what are further individual determinants of Paul's behavior?

a. Paul's short-term goals (e.g., Paul might be willing to present himself as an understanding person because he is in love with a colleague, Andrea, and wants to make a good impression).
b. Paul's long-term goals (e.g., Paul might have a job offer that he is planning to accept so that he doesn't care about the deadline).
c. Paul's general interests, motivations, and beliefs (e.g., Paul might believe that everyone is responsible for his or her own good and, thus, does not feel responsible for Andrea).
d. Personality traits (i.e., Paul could be a highly agreeable person increasing the probability for respectful behavior in this specific situation).

Last but not least, the characteristics of the situation as well as the cultural context will influence his behavior (e.g., Paul might adjust his behavior when he finds Andrea drenched in tears after a conversation with her husband. If the corporation has a good working atmosphere, the probability of him being more understanding is greater).

Considering all the aforementioned characteristics and behavioral alternatives, what determines whether Paul can be evaluated as socially competent? Is it enough to possess the cognitive and behavioral resources (1–3) so that he could behave competently if he wanted to? Is he only a socially competent person when he attains his personal goals? Or is it necessary that his behavior, those short- or long-term goals or

his beliefs (a–d) which guided his behavior, are socially acceptable?

The above list of individual resources may not be exhaustive and does not go into the details of the concepts mentioned. It does not address how the different abilities and skills overlap or affect each other. However, it exemplifies the following terminological specifications.

Intelligence versus Competencies

The concepts of intelligence and competence are often applied as synonyms (Süß et al., 2005). Some distinctive features commonly accepted in the literature are the context-specificity of competence (Kanning, 2002; McFall, 1982) and the more general meaning of intelligence constructs across situations or contexts (Süß et al., 2005). Competence appears to be more subject to modification and learning (Rose-Krasnor, 1997), whereas intelligence is comparatively stable over time and seen as hereditary to a large extent (see Deary et al., 2006 for an overview). However, intelligence is often a necessary part of the evaluation of competence (Süß et al., 2005).

Abilities versus Skills

According to Scherer (2007), behavioral or cognitive skills are concrete actions or applications of cognitive operations on concretely defined problems (e.g., driving with a stick shift or applying an algorithm on new data). Skills are acquired in a process of several steps and are finally characterized by an automated series of actions (Ackerman, 1987). Thus, there is reason to infer that skills are either the successful application of situation-specific knowledge or even procedural knowledge itself. In contrast, abilities are only cognitive in nature and represent more general, dispositional capacities (Süß et al., 2005). They typically constitute intelligence constructs (e.g., reasoning ability) and thus, are "either genetically endowed or acquired over a long period of socialization" (Scherer, 2007, p. 103). Besides abilities, skills are typically part of an evaluation of competence.

Potential versus Behavioral Performance

The individual's potential represents all resources of a person, which are necessary to allow competent behavior (i.e., the result) (Süß et al., 2005). Results-oriented approaches understand social competence as effective and/or socially accepted behavior where effectiveness/social acceptance is determined through the degree of goal attainment, specific properties of the situation, and the person who assesses whether and to what degree the behavior points toward social competence (McFall, 1982; Rose-Krasnor, 1997). Whether a person shows effective behavior is not a deterministic function of his or her potential. Additionally, it depends on the person's priorities (e.g., motivation and goals), his or her personality (e.g., extraversion and agreeableness), current states (e.g., fear, exhaustion, and distraction), and on situational and context variables (e.g., broad cultural or group values) (Süß et al., 2005).

While the distinction between potential and result is self-evident in research focusing on abstract academic intelligence (i.e., assessing indicators of job performance as behavioral criterion to prove predictive validity of intelligence constructs), this may not apply in the context of social intelligence, where results-oriented approaches are frequently applied to conclude from behavior to the potential (e.g., Assessment Center exercises; Hoffman et al., 2011).

Requirements for an Intelligence Construct

With the introduction of new constructs, the diversity of labels (e.g., social skills, social and emotional competence and intelligence, and successful intelligence) and assessment approaches (e.g., ability tests, self-report inventories, and Situational Judgment Tests) has increased. However, there are many conceptual and methodological requirements to determine how well an intelligence construct is established (Landy, 2006; Matthews et al., 2005; Schaie, 2001; Weber and Westmeyer, 2001). Some commonly agreed upon requirements established in the literature are (see also Conzelmann et al., 2013):

1. Theory and construct specification
   Matthews et al. (2005) require a priori theoretical considerations on the "localization of the intended construct within the sphere of individual differences" (p. 80). O'Sullivan (1983) demands a clear and nonredundant terminology while Süß (2001) asks for an empirical foundation. Additionally, constructs and subconstructs need to be defined and categorized taking existing hierarchical structures including broad, cognitive determinants (Carroll, 1993) into account which are relatively stable over time and contain a minimum amount of knowledge (Süß, 2001).

2. Operationalizations and validation
   With respect to the psychometric qualities, Matthews et al. (2005) and Weber and Westmeyer (2001) demand psychometrically sound operationalizations congruent with construct specifications (O'Sullivan, 1983). Moreover, performance tests should be applied (Süß, 2001; Weber and Westmeyer, 2001) in the sense of Cattell's conception of T-data (Cattell, 1965). To investigate the convergent and divergent construct validity, adequate operationalizations for the construct of reference have to be selected (Schaie, 2001). Concerning criterion validity, studies have to provide evidence for the incremental predictive validity of heterogeneous external criteria over and above traditional predictor variables (Süß, 2001).

3. Other requirements
   Genetic determination to a reasonable extent is an unquestioned requirement (Austin and Saklofske, 2005), whereas there is no agreement about a positive correlation to age due to increased experience as postulated by Schaie (2001). The latter is in conflict with the requirement of only a minimum amount of knowledge in construct specifications (Süß, 2001). Moreover, it contradicts findings about fluid intelligence yielding a generally curvilinear relationship with age (Schaie, 1994).
   Among others, Austin and Saklofske (2005), Gottfredson (2003) and Neubauer and Freudenthaler (2005) all demand positive correlations between tasks of academic and new intelligence constructs to underpin the idea of the

positive manifold (Jensen, 1998). This view is questioned by some other groups of researchers (e.g., Guttman, 1992; Henry et al., 2005; Horn, 1985). For a comprehensive picture of the entire debate, see Bowman et al. (2002). At the moment, there appears to be no necessity to assume positive correlations with academic intelligence as a 'conditio sine qua non' for new intelligence constructs.

Social Intelligence

In a model of social competence, social intelligence represents one of the core individual resources. Several literature reviews exist (Landy, 2006; Walker and Foley, 1973; Weis and Süß, 2005) which sum up the research history that was castigated by Landy (2006) as a 'long, frustrating, and fruitless search.' The problems are manifold: definitions did not differentiate between cognitive and behavioral requirements, or abilities and skills (Conzelmann et al., 2013). Frequently, self-report inventories were applied (Riggio, 1986). The majority of performance tests were based on verbal material only (e.g., Chapin Social Insight Test; Chapin, 1967) and showed no divergent construct validity with tests of academic intelligence.

The following sections intend to give an overview of the conceptual basis of social intelligence as a cognitive ability construct of existing measurement approaches and of current data.

Theoretical Models

Apart from numerous single definitions, two more comprehensive theoretical approaches are apparent in the literature. Guilford's Structure of Intellect Model (Guilford, 1967) integrates a social content component in addition to abstract academic abilities that results in 30 distinct ability factors of social intelligence (in a revision of the model assumed to be correlated). The entire model, however, was not supported by data (Brody, 2000). Weis and Süß (2005) classify existing definitions as all addressing some social cognitive ability. This resulted in a Model of Social Intelligence based on four presumably correlated social cognitive ability factors (i.e., understanding, memory, perception, and flexibility) plus social knowledge and a higher-order social intelligence factor. Social knowledge, however, is not seen to rely on only cognitive requirements because knowledge contents always depend on situational or cultural influences. For a list of concepts and labels assigned to the four ability domains, see Conzelmann et al. (2013). The four domains were specified as follows:

- Social understanding (also social inference, social interpretation, or social judgment): the ability to understand social stimuli against the background of the given social situation.
- Social memory: the ability to store and recall objectively given social information that can vary in complexity.
- Social perception: the ability to perceive socially relevant information quickly in fairly complex situations.
- Social flexibility: the ability to produce as many and as diverse solutions or explanations as possible for a social situation or a social problem.

The model was partly supported in a multitrait–multimethod study (Weis and Süß, 2007) applying established tests for social understanding and social knowledge and newly constructed tests for social memory. The confirmatory factor model showing the best fit specified three separable but correlated ability factors (i.e., social understanding, social memory, and social knowledge) and one method factor with loadings of all tests based on verbal material (i.e., written language). However, social memory was not sufficiently distinguishable from academic intelligence (Conzelmann et al., 2013) to be considered as a unique social intelligence factor.

The relationship of social to emotional intelligence has not so far been developed in detail. On a broad construct level, several researchers agree on an as yet unspecified overlap (Davies et al., 1998; Mayer et al., 2000). Few studies have investigated the relationship (Davies et al., 1998; Weis and Süß, 2007) and those have found inconsistent results. Regarding the Four Branch Model of Emotional Intelligence (Mayer et al., 2000) and the above-mentioned Model of Social Intelligence (Conzelmann et al., 2013), the domains of perception and understanding are represented in both models. Meanwhile, social contents cover information about emotions but also reach further. However, the question of construct overlap needs more profound empirical clarification based on measures derived from and validated by these or other theoretical models.

Measurement Approaches

In this report, we are only focusing on cognitive ability tests and are omitting self-reported inventories and behavior-based approaches because they do not comply with the aforementioned requirements. Compared to the construction of academic intelligence tests, no comparable body of rules is available for items or tasks of social intelligence. In contrast to tasks such as number series, the item pool is not documented and possibly not even available. The particular tasks that measure social cognitive abilities are not specifically taught in institutional settings. Therefore, numerous characteristics of social intelligence tasks can be identified. **Table 1** provides exemplary psychometric tests representative for the variability of measurement approaches:

- Comprehensive test batteries based on theoretical models (e.g., Magdeburg Test of Social Intelligence, MTSI, Conzelmann et al., 2013) versus single modalities.
- Different task materials (i.e., written and spoken language, pictures, and videos).
- Different item characteristics (i.e., item origin, stimulus properties, and context information).
- Different formal characteristics (i.e., response format and scoring).
- Different queried modalities in social understanding tasks (i.e., what modality has the subject to infer about such as emotions, thoughts, and relationships).

Additionally, **Table 1** contains short global validity information. For reasons of comparison, the Model of Social Intelligence (Conzelmann et al., 2013) serves as a frame of reference for the classifications of task requirements.

Empirical evidence concerning the convergent and discriminant construct validity is equivocal and varies

Table 1 Characteristics of social cognitive ability tasks showing representative example tests

substantially in connection with task characteristics just as does the psychometric quality (see Weis and Süß, 2005 for a review). To summarize, applying decontextualized, artificially produced material based on written language resulted in substantial correlations with tasks of abstract academic intelligence, thus questioning the discriminant construct validity (e.g., Chapin Social Insight Test, Chapin, 1967). Additionally, not accounting for the queried modality seemed to impair convergent construct validity (Ambady et al., 2001), just as did different response formats.

Tasks of social understanding that require inferring the mental states of target individuals or offering possible explanations or solutions for complex social problems carry additional problems. Particularly, the application of equivocal stimuli without context information makes inference about any mental state highly difficult or even impossible. Another, so far unsolved problem demonstrated in research on emotional intelligence, is the scoring of tasks when no standard (i.e., objectively correct answer) is available. All scoring methods apart from standards-based scoring (i.e., target scoring and expert or group consensus scoring) carry different problems (see Conzelmann et al., 2013 for a discussion). In short, we consider target scoring rather than expert or group consensus scoring as the best known approximation to objective scoring when questions of social desirability are accounted for and the target's mental state can be defined by means of standardized procedures.

As a conclusion from the above considerations and the empirical literature, the MTSI (Conzelmann et al., 2013) was developed to account for some necessary requirements for social cognitive abilities tasks:

- Theoretical foundation: Task and item construction was founded in the Model of Social Intelligence.
- Multitrait–multimethod/multimodality designs: The systematic variation of task material (i.e., written and spoken language, pictures, and videos) resulted in better interpretable validity evidence and a smaller overlap with the abstract academic intelligence of past studies (Weis and Süß, 2007; Wong et al., 1995).
- Origin of stimulus material: In contrast to artificial or posed material, stimuli with real-life origins (i.e., particularly material other than written language) enhance the ecological validity and the acceptance and promote discriminant construct validity with abstract academic intelligence (e.g., IPT-15, Costanzo and Archer, 1993). Moreover, target information or even objective standards can be sampled for scoring. Transfer to real-life situations is more probable.

- Context information: Tasks with equivocal stimulus material (i.e., tasks of social understanding) should provide enough context information to allow correct inferences. When context information is embedded in stimulus material, it should be varied systematically in order to reduce the context- or situation-specific influence (e.g., through experience or knowledge) to a minimum.

Finally, social intelligence as assessed by existing measurement approaches still lacks evidence for its predictive validity in relevant, real-life outcome criteria. One criterion validity study was conducted by Hampel et al. (2011) applying the MTSI and finding the theory-consistent relations with the level of social anxiety in a general population sample.

Social Competence

We consider social competence as the entity of all individual resources (i.e., the potential) necessary to show social competent behavior in varying types of applied settings (adapted from Kanning, 2002). The following sections give an overview of existing conceptual approaches and integrate them into a framework of social competent behavior. Later, measurement issues are addressed.

Concepts: Comparison and Integration

Definitions of social competence vary substantially according to the spectrum of covered human attributes from just one characteristic (e.g., management of conflict and communication skills) to a complex interaction of assorted variables (see Rose-Krasnor, 1997; Nangle et al., 2010 for reviews). They may either focus on the person's potential, or the behavioral result, or a mixture of both. Additionally, some definitions only incorporate concepts, which allow a evaluation of a person's underlying competence as opposed to definitions that also include individual dispositions or traits (e.g., personality and motivation), not allowing an evaluation of 'better or worse' (Rose-Krasnor, 1997; Schneider et al., 1996). **Table 2** contrasts some selected, comprehensive, and representative approaches.

By definition, the four approaches (**Table 2**) show substantial differences. McFall (1982) developed a process model, which allows for individual characteristics (i.e., skills) besides situational variables, behavior, and the person who evaluates the behavior. Contrary to the other three mentioned, Schneider et al. (1996) conceive social competence as independent from situations, and assessment about the level of competence is only based on the degree of goal attainment. This is in contrast to social acceptance which is relevant in the concepts of Rose-Krasnor (1997) and Kanning (2002).

Table 2 Definitions of social competence

		McFall (1982)	*Schneider et al. (1996)*	*Rose-Krasnor (1997)*	*Kanning (2002)*
Definitions		"Social skills are defined [ ] as the specific abilities that enable a person to perform competently at particular social tasks." (p. 23) "Competence is a generally evaluative term that reflects somebody's judgment, on the basis of certain criteria, that a person's performance on some task is adequate." (p. 13)	"We define social competence as socially effective behavior and its cognitive, affective and conative antecedents. Socially effective behavior is behavior that is instrumental in helping people achieve personal goals that are social in nature." (p. 471)	"… effectiveness in interaction, considered from both self and other perspectives. Social competence is viewed as an organizing construct, with transactional, context-dependent, performance oriented, and goal-specific characteristics." (p. 123)	Entity of a person's knowledge, abilities, and skills which promote socially competent behavior (=context-specific behavior for attaining a personal goal accounting for the social acceptance of the behavior).
Domains	Abilities	(Skills specified as abilities, see definitions above)	Social intelligence (social insight, memory, knowledge)	Emotional understanding	Social perception
	Skills/ knowledge	Decoding skills, decision skills, encoding skills	Social skills, social self-regulation	Problem-solving skills, communication skills, self-control	Behavioral control, assertiveness, communication skills
	Traits	–	Interpersonal personality traits	Motivation, personality traits, prosocial behavior	Social orientation
Orientation		Process	Potential and behavior	Behavior	Potential
Specific to situation		Yes	No	Yes	Yes
Evaluating perspective		Evaluator (x situation x performer)	Goal attainment	Goal attainment and social acceptance	Goal attainment and social acceptance

Table adapted and complemented from Süß, H-M., Weis, S., Seidel, K., 2005. Soziale Kompetenzen [Social Competences]. In: Weber, H., Rammsayer, T. (Eds.), Handbuch der Persönlichkeitspsychologie und Differentiellen Psychologie, (Reihe Handbuch der Psychologie) [Handbook of Personality Psychology and Differential Psychology]. Hogrefe, Göttingen, pp. 350–362.

However, leaving the broad level of definitions and looking at the single postulated dimensions of social competence, the approaches overlap. Except for McFall's process model that relies only on social skills, the remaining three approaches incorporate abilities (e.g., emotional understanding and social perception), skills (e.g., decoding skills and self-control), as well as behavioral dispositions (e.g., social orientation, personality traits, and motivation).

Based on the above-mentioned predefinitions, concepts are integrated into a framework of socially competent behavior (see **Figure 1**; modified based on Süß et al., 2005).

Summarizing the above considerations, the framework is specified as follows:

1. Social competence consists of a person's potential and does not include overt behavior in applied setting.
2. The person's potential only includes those constructs and concepts that allow a evaluation of 'better or worse' (i.e., abilities and skills). Any dispositional constructs (i.e., personality and attitudes) are left out although we acknowledge that they ultimately influence the probability of social competent behavior.
3. Within the person's potential, cognitive abilities (i.e., social and emotional intelligence, which are assumed to overlap), skills, and knowledge concepts are clearly differentiated. Abilities are broad, situation independent, relatively stable, and cognitive in nature. Skills are situation specific, subject to modification and learning, and can refer to cognitive operations or behavioral sequences. In contrast to socially competent behavior in applied settings, social behavioral skills are more elementary and instead represent the microscopic level of human behavior. Therefore, the application of skills always stands in relation with situational variables but is typically not influenced by an individual's dispositions and is independent of the person who evaluates the behavior. Declarative knowledge refers to explicit knowledge (e.g., social rules, socially relevant situational scripts, or situation-specific patterns of emotional reactions). Procedural knowledge, typically, is implicit knowledge which cannot be explicitly learned or taught or deliberately recalled (e.g., how to use the tone of voice to convey or trigger a certain feeling, how to apply heuristics in order to choose the best behavioral alternative). The gap between procedural knowledge and the application of it in the form of cognitive or behavioral skills cannot be filled in by drawing upon the literature. This gap appears to be rather small if it exists at all, particularly when measurement opportunities are considered (see next section).
4. Socially competent behavior is predicted by the individual's level of social competence (represented by the solid arrows in **Figure 1**) over and above variables in disposition or temperament. As indicated by the different strength of the

Note. Continuous arrows = prediction (predictor–criterion-relationship)
broken arrow = process of skill / knowledge acquisition
dotted arrow = evaluation (arrowhead points toward behavior/goal to be evaluated)

Figure 1 Framework of social competence and socially competent behavior.

arrows, we assume a larger predictive power of skills and knowledge compared to abilities that are due to construct and measurement similarities. Moreover, social cognitive abilities, social skills, and declarative knowledge are assumed to be positively related constructs.

5. In accordance with the PPIK-Theory (i.e., Process–Personality–Interest–Knowledge, Ackerman, 1996), skills (seen as almost equal to procedural knowledge) and declarative knowledge are acquired by the investment of fluid intelligence (i.e., social and emotional intelligence) into areas of interest and which fit to the individual's personality (indicated by the broken arrows in **Figure 1**).
6. Abilities and declarative knowledge are typically assessed by psychometric tests so that the assessment (indicated by dotted arrows in **Figure 1**) of 'more or less able' or 'more or less knowing' is based on the test score independent of an analyzing perspective (i.e., objectivity). Measuring procedural knowledge or skills is more difficult although still remains independent of subjective interpretation. Whether the demonstration of social behavior is evaluated as socially competent primarily depends on the attainment of the behavioral goals of the individual. Additionally, when social behavior (or its underlying goal) is evaluated based on its social acceptance, the evaluating perspective needs to be considered as well (e.g., individuals from different cultural backgrounds or different peer groups may find differing behavioral actions socially acceptable) (McFall, 1982). These assumptions also mean that an assessment of an individual's social competence based only on his or her behavior in highly complex, applied situations should not be done or only done carefully when a goal is not predetermined (e.g., selection situations) and the situation allows unsystematic influences of conflicting variables that should not be the basis for assessment (e.g., the relevant peer group is not known). In such situations, several reasons for showing or not showing socially competent behavior may exist apart from a lack of social competence.

Measurement and Design Issues

The landscape of measurement approaches for social skills and social behavior is even more heterogeneous than for social intelligence. **Table 3** presents three classes of measurement approaches (i.e., inventories, knowledge tests, and behavioral assessment) cross-classified with constructs including a global assessment of the construction efforts, the possibility of response distortion, and the objectivity. (For a more profound review of measurement approaches to assess social and emotional skills in children and young people, see Humphrey et al., 2011.)

Self-reported and other similar inventories are easily constructed and highly objective but carry the problem of response distortion, particularly in relation with constructs involving evaluation. Implicit knowledge tests (also Situational Judgment Tests, see McDaniel et al., 2007 for a meta-analysis) allow an objective assessment of procedural knowledge and cognitive and behavioral skills that typically cannot be distorted by the subject. The testing principle presents a description of a situation and a number of answering alternatives providing explanations, solutions, or possible behavioral actions. In multiple choice or ratings-based items, individuals have to evaluate the effectiveness of the behavioral actions for solving a given problem or reaching a goal. Although item contents frequently address the behavior, the *knowledge* about behavior is assessed instead ($\approx$procedural knowledge $\approx$ cognitive and behavioral skills). The last category of measurement approaches comprises behavioral observation methods. Observations can be done in experimental or applied settings (e.g., Assessment Center exercises such as role plays). To evaluate social skills or procedural knowledge, specific experimental settings would be required to provoke people to show their ideal behavior and to reduce variance due to states or confounding personality variables in applied settings (e.g., through instructional variations). Socially competent behavior should be assessed in applied settings or, at least, settings with a certain level of complexity so that an average behavioral reaction has little or no chance of occurring. Behavioral observation is a highly complex research field of its own and the problems are multifaceted (i.e., reactivity and participatory observation; social desirability, finding an adequate rating system and inter-rater-reliability; time versus event sampling; and interdependence with exercise; see Hoffman et al., 2011).

Across all three types of measurement approaches, situational variability is a relevant feature. Nangle et al. (2011) provide some examples of (incomplete) classification systems of situations or social tasks and stress their importance not only for purposes of conceptualization and measurement but also for the identification of treatment opportunities. Additionally, specifying the characteristics of the situation also helps in evaluating the degree of generalization of empirical findings.

As pictured in **Figure 1**, socially competent behavior is the outcome of social competence which brings us back to the lack of criterion validity studies for social intelligence. Examining the specifications of the above framework not only provides information about the model itself, but also about the criterion validity of social intelligence given an adequate selection of

Table 3 Categories of measurement approaches to assess procedural knowledge, skills, and behavior

	Procedural knowledge/skills			*Behavior*		
	Construction effort	*Response distortion*	*Objectivity*	*Construction effort*	*Response distortion*	*Objectivity*
Self- and other report	Low	High	High	Low	High	High
(Implicit) knowledge test	High	Low	High		–	
Behavioral observation	High	Low	High	High	Medium	Low

relevant behavioral outcome criteria. In this respect, Lievens and Chan (2010) suggest to determine thoroughly what social intelligence should be valid for and what not. For example, they miss a theoretical basis for investigating the prediction of academic performance by emotional intelligence. In general, the predictive value of social intelligence, knowledge, and skills is different depending on the chosen outcome criterion. Moreover, the selection of outcome criteria needs to consider the hierarchical structures of predictors and criteria (Brunswik, 1956). Only when symmetrical levels in the hierarchy are chosen, the maximum predictability is achieved.

Conclusion

Particularly in the last sections, more questions were posed than answered. And we cannot, at that point, evaluate whether Paul – remember our leading character in the introduction – is a socially competent person without acknowledging several situational characteristics and his behavioral goals which we currently do not know about. To progress substantially in this field of research, several challenges need to be conquered. Conceptual issues have to be addressed empirically (e.g., the suggested framework of socially competent behavior requires empirical substantiation through multivariate research designs). Future research should focus on the development and improvement of measures of not only abilities but also procedural and declarative social knowledge and social skills. Several methodological problems have to be faced of which only one important is the development and use of a scoring procedure that is as objective as possible. In the field of social and emotional intelligence, some objective tests are already being applied (e.g., Conzelmann et al., 2013; Wilhelm et al., 2010), but it will be important to examine to which degree such an objective approach is possible taking into account the aforementioned complexity of the variables. Identifying both, the sources of situational variability (i.e., what are situational attributes that contribute to the variability in social behavior) and adequate and relevant real-life outcome criteria for social intelligence, should be further major aims. The latter is a particularly challenging issue since adequate social criteria are often highly specific and make transfer to practice very difficult. Although we mainly have dealt with the potential of an individual what is considered to be subject of change to only a limited degree, the extent to which trainability is possible (i.e., particularly considering the level of knowledge and skills) has to be investigated.

Last but not least, researchers who want to face these challenges should, at the very beginning of the undertaking, clarify whether social competence is conceived a value-free concept in the sense that not the behavioral goals are evaluated but only the degree of goal attainment. Otherwise, the value of not only goals but also personality characteristics needs to be identified (e.g., against the cultural background) prior to determine the degree of social competence. Facing these challenges and making progress seems to be a hard but worthwhile task. Should there be objective, reliable, and valid measures for social abilities, knowledge and skills, and appropriate methods to train aspects of the discussed constructs in the future, many different applied settings both personal and work could profit.

Social Intervention in Psychiatric Disorders

Wulf Rössler, Leuphana University Lüneburg, Lüneburg, Germany; University of Sao Paulo, Sao Paulo, Brazil; and University of Zurich, Zurich, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Serious mental illness can devastate the lives of people who suffer from it. These persons have a right to be treated according to current knowledge. Psychosocial interventions aim at reintegrating the mentally ill into the community and improving their quality of life. The goal of psychosocial intervention is to help disabled individuals to establish the emotional, social, and intellectual skills needed to live, learn, and work in the community with the least amount of professional support. The refinement of all these approaches has achieved a level where they should be made readily available for every person with severe mental disorders.

The objective of psychiatric reforms since the mid-1950s has been to resettle chronically mentally ill patients from large custodial institutions to community settings. Reform practice has changed the perception of mental illness. Enabling disabled persons to live a normal life in the community causes a shift away from a focus on an illness model toward a model of functional disability. Social role functioning including social relationships, work and leisure, as well as quality of life of the persons affected developed as a core target of psychosocial interventions. The overall philosophy of psychosocial interventions comprises two intervention strategies: the first psychosocial strategy is individual-centered and aims at developing the patient's skill in interacting with a stressful environment. The second psychosocial strategy is an ecological approach directed toward developing environmental resources to reduce potential stressors. Most disabled persons need a combination of both approaches. On more specific individual-centered levels, social interventions encompass social skills training, family intervention, and vocational training. Reducing potential stressors in the environment include the provision of sheltered living accommodation and work. Also financial resources have to be secured to meet basic needs. The article explains in detail the theoretical background as well as several psychosocial intervention strategies.

As early as the nineteenth century psychiatrists already suspected that harmful influences from the social environment might promote the appearance of mental illnesses or have a deleterious effect on their course. In that era, the isolation of the mentally ill in the 'healthful' milieu of institutions far removed from their original living environment was thought to be an appropriate means of shielding the patients from the disease-producing influences of their surroundings. The objective of psychiatric reforms since the mid- to late 1950s was to resettle chronically mentally ill persons from large custodial institutions to community settings. The idea behind this was to (re-)integrate patients in their normal living environment as rapidly as possible, because it was thought that their natural social network would make a major supporting contribution to the healing process (Rössler, 2001).

This reform has changed the perception of mental illness. Enabling disabled persons to live a normal life in the community caused a shift away from a focus on an illness model toward a model of functional disability (Grove, 1994). As such, other outcome measures aside from clinical conditions became relevant. Since then social role functioning including social relationships, work, and leisure, as well as quality of life and the family burden, became of major interest for affected individuals living in the community as well as for the health professionals involved in treatment and care of those persons (Rössler, 2000).

In the current scientific discourse, environmental and psychosocial factors are often relegated to the status of a single variable of merely peripheral interest, without further specification. Biological science has indeed made enormous progress toward an understanding of mental disorders, but it should not be forgotten that research in social sciences also yielded a considerable body of knowledge with respect to the psychosocial and environmental factors that influence it (Rössler, 2001).

The relevance of psychosocial and environmental problems is also reflected in the DSM IV and ICD-10. Axis 4 of the DSM (American Psychiatric Association, 1994) and codes Z 55–Z 65 and Z 73 of the ICD-10 (WHO, 1993) are assigned for reporting psychosocial and environmental problems that may affect the diagnosis, treatment, and prognosis of mental disorders. The importance of role functioning when it comes to 'clinical judgment' is also emphasized in the newly launched DSM-5 (Maj, 2013).

Target Population of Psychosocial Interventions

Although the majority of the chronically mentally ill have the diagnosis of schizophrenic disorders, other patient groups with psychotic and nonpsychotic disorders are also targeted by psychosocial interventions. All patients suffering from severe mental illness (SMI) now require psychosocial interventions. The core group is drawn from patients with:

- persistent psychopathology
- marked instability characterized by frequent relapses, and
- social maladaptation (Royal College of Psychiatrists, 1996).

There are other definitions currently used to characterize the chronically mentally ill, but they all share some common

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27067-0

elements, i.e., a diagnosis of mental illness, prolonged duration, and role incapacity.

Furthermore, up to 50% of persons with SMI carry dual diagnoses, especially in combination with substance abuse (Cuffel, 1996). Young adult chronic patients constitute an additional category that is diagnostically more complicated (Schwartz et al., 1983). These patients present complex pictures of symptomatology difficult to categorize within our diagnostic and classification systems. Many of them also have a history of suicide attempts. All in all, they represent a patient population that is mostly difficult to treat.

Models of Vulnerability

There are several vulnerability–stress models forming the theoretical basis into which biological and social intervention approaches of psychiatric treatment, rehabilitation, and care can be integrated. These models were developed mainly for persons with schizophrenic disorders, but they apply essentially to all individuals with SMI.

In the *vulnerability–stress* model it is presumed that socio-environmental stressors superimposed on an underlying and enduring biological vulnerability lead to abnormalities in central nervous system functioning (Zubin and Spring, 1977). In the *vulnerability–stress–competence* model (Nuechterlein and Dawson, 1984), individuals, families, and natural support systems can cope with stressors and have the competence to create a higher threshold for symptomatic illness. In an *interactive–developmental* model (Strauss et al., 1981), the persons affected do not remain in a passive role but actively interact with their environment. They modulate and select the kind of help they get from other people, they choose to comply with the treatment, and they seek or avoid social support and stressful situations.

The interactive–developmental model is the basis for the consumer movement in mental health care. People with mental disorders and their caregivers prefer to see themselves as consumers of mental health services with an active interest in learning about psychiatric disorders and in selecting the respective treatment approaches. Consumerism makes it possible to take up the affected person's perspective and to consider seriously courses of action relevant to them (Kopelowicz and Liberman, 1995).

Conceptual Framework of Psychosocial Interventions

The overall philosophy of social interventions in psychiatric disorders comprises two intervention strategies: the first strategy is individual-centered and aims at developing the patient's skill in interacting with a stressful environment. There is no consensus among researchers as to what this individual-centered approach actually does accomplish. Some understand developing patient's skill as an approach to help disabled persons to compensate for impairments and to function optimally with the deficiencies they have. Others assume that different forms of individual-centered interventions help with recovery from the disorder itself, while the contributing factors to the healing process are not clear (Strauss, 1986).

The second strategy is an ecological approach directed toward developing environmental resources to reduce potential stressors. This approach includes psychosocial interventions concerning housing and occupation as well as measures to build natural networks, as many chronically mentally ill and disabled persons lose close and stable relationships in the course of the disease. Most disabled persons need a combination of both approaches.

In contrast to acute treatment there are mostly no legal powers to enforce psychosocial interventions in long-term care. Thus, the sufferer's autonomy concerning treatment decisions should be respected. Within this frame, therapeutic alliance plays a crucially important role in engaging the affected persons in their own care planning. As such, the therapist should acknowledge that disagreement about the illness between patient and therapist is not always the result of the illness process (Eichenberger and Rössler, 2000).

The International Classification of Functioning, Disability and Health

The long-term consequences of major mental disorders targeted by psychosocial interventions might be described on different levels. A useful framework is provided by the 'International Classification of Impairment, Disability, and Handicaps' (WHO, 1980) and by the revised version of this classification, i.e., the 'International Classification of Functioning, Disability and Health' (WHO, 2001). The revised International Classification of Functioning, Disability and Health (ICF) (4) includes a change from negative descriptions of impairments, disabilities and handicaps to neutral descriptions of body structure and function, activities and participation. A further change has been the inclusion of a section on environmental factors as part of the classification. This is in recognition of the importance of the role of environmental factors in either facilitating functioning or creating barriers for people with disabilities. Environmental factors interact with a given health condition to create a disability or restore functioning, depending on whether the environmental factor is a facilitator or a barrier.

The ICF is a useful tool to comprehend mentally ill in all their dimensions, including impairments at the structural or functional level of the body, at the person level with respect to activity limitations, and at the societal level with respect to restrictions of participation. Each level encompasses a theoretical foundation on which a psychosocial intervention can be formulated.

In addition to acute symptoms, chronically mentally ill patients have impairments in the most basic cognitive processes concerning information input, memory, and abstraction. These cognitive impairments are present even when all symptoms have subsided, and they seem to be enduring markers of a vulnerability to the illness. Persistent and severe impairments lead to persisting limitations, i.e., affected persons will be limited in performing certain roles in their social and occupational environment. Finally, restrictions in participation occur when impairments and persisting limitations place the individual at a disadvantage relative to others in society.

On more specified levels concerning impairments, medication and cognitive training are provided. Effective pharmacotherapy and cognitive training stabilize affected persons so that they are more responsive to learning from their environment. Interventions concerning persisting limitations encompass mainly social skills training and family intervention. Furthermore, social interventions emphasize vocational training suitable to the extent of the handicap.

Reduction of Impairments

Medication

The interaction of medication and psychosocial interventions appear to be more than merely additive, as each can enhance the effects of the other. Some studies suggest that these agents improve the participation of patients on psychosocial interventions (Marder, 2000).

But even when taken regularly, medication is only able to reduce rather than abolish symptoms, and delay rather than prevent relapse. In addition to that, many of the traditional drugs have adverse effects and can weaken patients' ability to perform their social roles or can impair their social and vocational functioning. As such, it is not surprising that noncompliance with medication is one of the most serious problems in the long-term care of persons with SMI.

Several treatment strategies have been developed for improving compliance with medication. For patients with cognitive deficits, the complexity of the medication regimen should be reduced (Gaebel, 1997). Some patients need to be given the medication by a professional service on a regular basis. Depot medication (i.e., intramuscular injections that release the medication slowly into the bloodstream) might be especially useful for patients with fluctuating motivation or insight. It is also useful to involve families and caregivers in increasing compliance with medication.

Yet, many patients living in the community have to take responsibility for their medication themselves. Training in self-management of medication (Eckman et al., 1990) emphasizes the patient's autonomy and increases acceptance of and responsibility for treatment. This also includes variation of medication without consultation within certain limits.

Cognitive Training

With respect to cognitive deficits, consistent results emerged from most studies in so far as remediation of specific deficits through repeated practice or related techniques is successful. Current data suggest that it is effective when provided in a broader context of psychosocial interventions (Medalia and Saperstein, 2013).

One of the most promising comprehensive programs in this regard was developed by Brenner et al. (1992) since the 1980s. They called this program 'integrated psychological therapy' (IPT).

Over the past 30 years, research groups in 12 countries have evaluated IPT in 36 independent studies. Patients undergoing IPT showed significantly greater improvement in all outcome variables than control patients (Roder et al., 2011).

IPT comprises five stages: cognitive differentiation, social perception, communication skills, interpersonal problem solving, and social skills training. It is presented to groups of five to seven patients for 30–60 min two or three times a week. The hierarchically arranged program is aimed at facilitating acquisition and maintenance of more complex skills by remediating cognitive deficits.

Remediation of Persisting Limitations

Skills Training

In recent years, social skills training in psychiatric rehabilitation has become very popular and has been disseminated widely. The most prominent proponent of skills training is Robert Liberman, who has designed systematic and structured skills training since the mid-1970s. Liberman and his colleagues packaged the training in the form of modules which focus on different topics such as medication management, symptom management, substance abuse management, basic conversational skills, interpersonal problem solving, friendship and intimacy, recreation and leisure, workplace fundamentals, community (re-)entry, and family involvement. Each module is composed of skill areas. The symptom management module, for example, encompasses skills areas such as identifying warning signs of relapse, developing a relapse prevention plan, coping with persistent symptoms, and avoiding alcohol and drugs. The skills areas are taught in exercises with demonstration videos, role play and problem-solving exercises, and *in vivo* and homework assignments (Liberman, 1988).

The results of several controlled studies suggest that disabled individuals can be taught a wide range of social skills. Social and community functioning improve when the trained skills are relevant for the affected person's daily life, and the environment perceives and reinforces the changed behavior. Unlike medication effects, benefits from skills training occur more slowly. Furthermore, long-term training has to be provided for positive effects (Kurtz and Mueser, 2008).

Family Intervention

As a consequence of deinstitutionalization, the burden of care has fallen increasingly on the relatives of the mentally ill. It is estimated that up to 65% of mentally disabled individuals live with their families (Goldmann et al., 1981). This is a task many families do not choose voluntarily. Additionally, not all families are equally capable of giving full support to their disabled member, and may not be willing to replace an insufficient health care system (Johnson, 1990). But families also represent support systems, which provide natural settings for context-dependent learning important for recovery of functioning (Schooler, 1995). As such there has been a growing interest in helping families since the beginnings of care reforms (Strachan, 1986).

One area of interest dealt with the expectations of relatives concerning the provision of care. Relatives quite often feel ignored, not taken seriously, and insufficiently informed by health professionals. They also may feel that their contribution to care is not appreciated, or that they will be blamed for the patient's problems. It is certainly not surprising that there is a lot of frustration and resentment among relatives related to the extent of the physical, financial, and emotional family burden. As important research has demonstrated a relationship between a negative affective family atmosphere and an unfavorable course of a mental disorder, the need for helping

families and patients with family intervention programs became clear.

All family intervention programs include an educational aspect covering basic information on the etiology, treatment, and prognosis of schizophrenia. Although family interventions differ in the treatment focus, all family interventions are organized around the principal goal of providing family members with more information about the disorder and strategies for managing common problems. There are more common features: family interventions are concrete, practical, and focus on everyday coping.

Family intervention programs have produced the most promising results. Family intervention is effective for improving outcome (e.g., social functioning) (Koukia and Madianos, 2005). Possibly, family intervention can reduce family burden. Furthermore, the treatment gains are fairly stable (Pilling et al., 2002).

However, it is not clear what the effective components of the different models are. Additionally, family interventions differ in frequency and length of treatment. There are also no criteria for the minimum amount of treatment necessary (Barbato and D'Avanzo, 2000).

Finally, it should be noted that most of the family interventions were developed in the context of Western societies during deinstitutionalization. Family caregiving might be quite different in a different cultural context. This refers to other cultures in total as well as to minority groups in Western societies (Guarnaccia, 1998).

Enhancing Participation by Vocational Rehabilitation

The beneficial effects of work for mental health have been known for centuries (Harding et al., 1987). Vocational rehabilitation therefore has been a core element of psychiatric reforms since its beginnings.

Vocational rehabilitation is based on the assumption that work not only improves activity, social contacts, etc., but may also promote gains in related areas such as self-esteem and quality of life, as work and employment are a step away from dependency toward integration into society. Enhanced self-esteem in turn improves adherence to long-term care of individuals with impaired insight (McElroy, 1987).

Vocational rehabilitation originated in psychiatric institutions, where the lack of activity and stimulation led to apathy and withdrawal among their inpatients. Long before the introduction of medication, occupational and work therapy contributed to sustainable improvements in long-stay inpatients. Today occupational and work therapy are no longer hospital-based, but represent the starting point for a wide variety of rehabilitative techniques teaching vocational skills (Royal College of Psychiatrists/College of Occupational Therapists, 1992).

Vocational rehabilitation programs in the community provide a series of graded steps to promote job (re-)entry. For less disabled persons, brief and focused techniques are used to teach them how to find a job, fill out applications, and conduct employment interviews (Jacobs et al., 1988). In transitional employment a temporary work environment is provided to teach vocational skills that should enable the affected person to move on to competitive employment. But too often the gap between transitional and competitive employment is so large that the mentally disabled individuals remain in a temporary work environment. Sheltered workshops providing prevocational training also quite often prove to be a dead end for disabled persons.

One result of the difficulties of integrating mentally disabled individuals into the common labor market has been the steady growth of cooperatives which operate commercially with disabled and nondisabled staff working together on equal terms and sharing in management. The mental health professionals work in the background providing support and expertise (Grove, 1994). Cooperatives serve as a bridge between sheltered workshops and competitive jobs on the common labor market.

Today, the most promising vocational rehabilitation model is supported employment. In this model, disabled persons are placed in competitive employment as soon as possible and receive all the support needed to maintain their position. Skills are taught in the actual environment, tailored to the job and the individual. If necessary, additional advice is given to the employer. As the course of SMI is unpredictable and job requirements often change, the support provided is neither time-limited nor delivered on a fixed schedule (Wallace, 1998). Participation in supported employment programs is followed by an increase in the ability to find and keep employment (Burns et al., 2007). Today there is sufficient evidence of work having beneficial effects on clinical and social functioning (Catty et al., 2008; Burns et al., 2009; Kilian et al., 2012).

Although findings regarding supported employment are encouraging, some critical issues remain unanswered. Most individuals in supported employment obtain unskilled part-time jobs. Since most studies only evaluated short (12–18 months) follow-up periods, the long-term impact remains unclear.

It must be acknowledged that the integration into the labor market by no means depends exclusively on the ability of the persons affected to fulfill a work role and on the provision of sophisticated vocational training and support techniques, but also on the willingness of society to integrate its most disabled members.

Developing Environmental Resources

Effective community psychiatry requires individualized and specialized treatment, which has to be embedded in a comprehensive and coordinated system of community services. But even when a variety of services is available, they are poorly linked in many cases, and costly duplication may occur.

While developing community support systems it became obvious that there was a need to coordinate and integrate the services provided as each professional involved concentrates on different aspects of the same patient. Therefore, as a key coordinating and integrating mechanism, the concept of case management (CM) originated. CM focuses on all aspects of the physical and social environment. The core elements of CM are the assessment of patient needs, the development of comprehensive service plans for the patients, and arrangement of service delivery (Rössler et al., 1992).

Since the 1980s, a range of different models of CM have been developed which exceed the original idea that CM intends mainly to link the patient to needed services, and to coordinate those services. Today most clinical case managers

also provide direct services in the patient's natural environment. This model is called intensive case management (ICM). ICM is difficult to distinguish from assertive community treatment (ACT).

Stein and Test developed the basic compounds of ACT in the 1970s (Stein and Test, 1980). The original program was designed as a community-based alternative to hospital treatment for persons with severe mental illnesses. A comprehensive range of treatment, rehabilitation, and support services in the community is provided through a multidisciplinary team. ACT is characterized by an assertive outreach approach, i.e., interventions are provided mainly in the natural environment of the disabled individuals (Scott and Dixon, 1995). Research on CM and ACT indicates that these models can reduce time in hospital, but have only small or moderate effects on improving symptomatology and social functioning (Mueser et al., 1998). The debate over the effectiveness and efficiency of CM and ACT is on-going and subject of further trials (e.g., Bramesfeld et al., 2013).

Conclusions

The goal of psychosocial intervention is to help disabled individuals to establish the emotional, social, and intellectual skills needed to live, learn, and work in the community with the least amount of professional support (Anthony, 1979). The refinement of all these approaches as described has achieved a level where they should be made readily available for every person with severe mental disorders.

But we have to be aware that it is a long way to translate research into practice. In 1992, the National Institute of Mental Health, for example, funded the 'schizophrenia patient outcome research team' (PORT) to develop and disseminate recommendations for the treatment of schizophrenia based on existing scientific evidence. The recommendations and further updates address in essence all psychosocial interventions as presented above (Lehman and Steinwachs, 1998; Dixon et al., 2010). Lehman and colleagues assessed the patterns of usual care for schizophrenic patients and examined the conformance rate with the PORT treatment recommendations. The conformance rate was modest. As such, it is obvious that current care practice has to be improved substantially in the light of the outcome research available (Dixon et al., 2010).

Serious mental illness can devastate the lives of people who suffer from it. These persons have a right to be treated according to current knowledge. But mental illnesses are associated with a significant amount of stigma, resulting in social isolation and discrimination in housing, education, and employment opportunities. Mentally ill people are even disadvantaged in receiving appropriate treatment and care, so stigma and discrimination further increase the burden on affected persons and their relatives. Yet, social interventions aim at reintegrating the mentally ill into the community and improving their quality of life. For these reasons a responsive and open-minded environment is indispensable. Therefore, translating research into practice always encompasses combating stigma and discrimination of mental illnesses as well (World Psychiatric Association, 1999).

Social Justice and Criminal Justice

Abstract

This article describes and explores what is meant by the term social justice. Emphasis is given to social justice issues that pertain directly or indirectly to the study of crime and justice. To accomplish this, general definitions of social justice are described, and the origins of the term social justice are briefly discussed. Next, a series of topics related to the study and practice of social justice are presented and explored in turn. These topics include, though are not limited to, peacemaking criminology, restorative justice, victim advocacy, environmental justice, and prison abolition.

Introduction

Social justice is a broad concept, and has been used in a variety of ways to refer to subjects of interest to criminologists. In this article, we examine the concept 'social justice' and the various ways in which social justice concepts can and have been applied to the study of criminal justice and other related process, such as social justice in law and in the application of law.

To illustrate these different uses of social justice relevant concepts, we examine several areas in which social justice orientations have been employed to illustrate how the primary concern of social justice approaches and measures of equity and fairness can be produced, and the issues that need to be addressed to facilitate social justice outcomes. To accomplish this task, we first review general definitions of social justice. Next, we examine social justice-related literature related to several issues including: peacemaking criminology; restorative justice; victim advocacy; mental health; the prison abolition movement; environmental justice; social work; and public health.

In undertaking this review, it is important for the reader to bear in mind that in contemporary academic literature, the concept of social justice has been extended to a number of fields. Traditionally, criminologists associate the concept of social justice with the work of radical criminologists in the late 1960s and 1970s. The field of social justice research, however, has come a long way since then, and social justice approaches are applied in many different disciplines. To illustrate that point, our discussion is not confined to criminological applications of social justice ideas alone. Indeed, while social justice approaches are certainly important within specific areas of criminological research (e.g., peacemaking criminology; restorative justice; victim advocacy; etc.), important literatures on this topic have emerged on issues, such as environmental justice and equity and public health that should not be ignored because of the ways in which they illustrated the expanded concept of social justice.

Defining Social Justice and the History of Social Justice Research

The idea of social justice can be defined in broad or general terms, and in more restrictive or relative terms. The general definition applies at an abstract level, while relative definitions make the application of social justice concepts clear with respect to given applications of social justice principles.

To begin with the general definition, we can say that the idea of social justice is, in the first place, dependent upon an assumption that equality is a valued social norm. From this it follows that societies are just when they are organized and arranged in ways that facilitate equality, and unjust when they hamper equality. In this general sense, then, we can say that a society takes on social justice values when it is organized in ways that allow its members to achieve, economic, political and social equality. Other broad views of social justice imply that economic, political, and social equality are not simply characteristics of society, but rights of people. That is to say, all people have a right to economic, political, and social equality, and therefore, societies that are organized in ways that impede those forms of equality are unjust societies or societies in which social injustice is evident.

In this broad sense, social justice societies value not only equality, but larger values such as basic human rights all people should be able to obtain. Sometimes, these human rights are defined as those that allow all individuals within a society to live in dignity, and to experience respect.

Historically, this broad concept of social justice can be traced to the work of the Catholic religious scholar, Luigi Taparelli D'Azeglio in the 1840s (Novak, 2000). As a doctrine, the principles of social justice became an official part of Roman Catholic Church teaching beginning in 1931, and thus marked the first extensive evidence of a system of thought committed specifically to establishing conditions for social justice (Novak, 2000). This Catholic social justice tradition has had significant influence in South America, and was employed to promote the development of liberation theology by the Peruvian Roman Catholic priest, Gustavo Gutierrez in 1973 (Berryman, 1987). The religious origins of this social justice emphasis are quite strong, and it was not until the 1960s and 1970s that the concept of social justice began to filter into secular social movements and academic writings.

On the latter point, radical criminologists in the late 1960s and early 1970s, such as Tony Platt, Richard Quinney, Paul Takagi, and Herman and Julia Schwendinger were among the first criminologists to address social justice issues and to illustrate their importance. This was truly a unique approach since

their work was among the first work on the applications of social justice perspectives in any discipline. These individuals were among the group, who formed the journal *Social Justice* (previously called *Crime and Social Justice*), which published its first volume in 1974. These early radicals took a decidedly class-based theoretical approach to social justice, and analyzed the ways in which the economic structure in class societies prevents the achievement of social justice. Over the past four decades, this radical concept of social justice in relation to criminology and criminal justice has expanded in a variety of ways, and has been addressed in relation to peacemaking (Pepinsky and Quinney, 1991; Quinney and Wildeman, 1991), postmodern criminology (Milovanovic, 1997), critical criminology (Arrigo, 2000, 2001), and distributive (Spader, 1988), and restorative justice approaches (Arrigo and Schehr, 1998).

In the narrower sense, social justice concepts and approaches have been applied to specific issues, several of which we review below. These include, for example, discussions of social justice in relation to public health access and the distribution of medical services, with respect to environmental justice or distributive justice issues related to the distribution of toxic hazards and environmental penalties across communities based on their class, race, and ethnic characteristics, and the achievement of social justice for particular groups, such as the mentally ill, prison inmates, school children, women, etc. In this sense, the narrow applications and definitions of social justice are simply illustrations of how general social justice principles apply to specific affected groups that appear to suffer social justice deficits.

With respect to academic analysis of social justice issues and applications of social justice theories, Tyler et al. (1997) argue that four distinct waves of social justice research can be identified. The first wave of research addressed social justice issues from the perspective of relative deprivation theory. This research emphasis drew attention to the feeling of being relatively deprived in comparison to others. In this sense, the relative deprivation approach was not about the absolute qualities of social justice, or the theoretical identification of social justice, but instead focused on the psychological identification of social justice people make when comparing themselves to others. In that view, relative deprivation is a feeling or sense of injustice that stems from feeling or perceptions that one is deprived relative to others with respect to the unequal distributions of social and economic goods, resources, and services. Such feelings can exist at the individual level or at the social level as an indicator of similar psychological orientations felt by a group of like situated individuals.

The second wave of research attended to distributive justice concerns. Distributive justice examines how resources are distributed in social environments, and whether the distribution of those resources is equitable. The main issue here, then, is whether social and economic resources are distributed fairly in reference to some assumption concerning how resources ought to be distributed. Thus, the determination of equity in resource distribution is based on an assumption concerning the defining of fair and equitable. In the broadest sense, one might assume that resources should be fairly or evenly distributed across populations regardless of the personal or group characteristics of individuals. Since the question is one of distribution, the focus is on the end result rather than the process of distribution, though clearly, if the end result is unequal distribution, the distributive process itself is called into question.

During the third wave of research, the focus was narrowed to issues related to procedural justice. Here, the issue is not the end result or the fairness of distributions, but rather the focus is on the process used to make distributional decisions, and whether the process itself is fair and equitable. In this view, inequality in outcomes can be linked to inequality in the distributive process and in access to distributive mechanisms including the law.

The fourth wave drew attention to what Tyler et al. (1997) defined as redistributive justice. Here, we make a distinction between two forms of redistributive justice. In the narrower sense as used by Tyler et al. (1997), redistributive just relates to examining reactions to the breaking of law, a conceptualization of redistributive justice relevant to social psychology and criminology. In other fields, however, redistributive justice is among the broadest forms of social justice, and perhaps one with the longest history. In those areas, redistributive justice is linked to the establishment of societies based wholly in equity principles, and the redistribution, for example, of property is a key concern in socialist and Marxist theory. Since the late 1970s, this concept has also been linked to environmental justice research and movements, and to the observation that environmental laws ought to aid in redistributing environmental benefits and harms equitably.

In the sections that follow, we review social justice perspectives linked to several more specific though often overlapping approaches to illustrate the various ways in which social justice arguments have been applied.

Peacemaking and Social Justice

Peacemaking criminology, which developed from the work of Pepinksy and Quinney, is viewed as a critical element of critical criminology's orientation toward praxis (McEvoy and Gormally, 1997). Praxis is essentially the practice or policy implications, in this case, of critical theories of crime and justice. In the peacemaking view, social justice is achieved through the use of peacemaking policies, including those that can be applied to mediating and restoring the harms caused by crime. Peacemaking practices attempt to address the outcomes of social injustice and oppression. As a criminological approach, it begins with the observation that criminal justice practices are organized in ways that extend the forms of violence to which they supposedly respond, and facilitate the legal application of forms of oppression responsible for crime. In this sense, criminal justice is interpreted as an extension of the forms of injustice that already characterize society. As a form of injustice, crime is viewed as emerging from forms of suffering, such as racism, economic and class inequality, poverty, alienation, and so on, that are part of the organizing structure of a society. In contrast to dominant social values like competition and penal values, such as retribution, peacemaking argues that the pathway to social justice and human fulfillment is establishing conditions for peace and love. For many criminologists, thinking about the problem of crime in this way, particularly with respect to concepts such as peace and love, are off-putting

and beyond the scientific image criminology has long sought to build. In this sense, peacemaking criminology has often been criticized as subjective, utopian, and soft on crime (for criticisms, see Akers and Sellers, 2009). Nevertheless, with respect to issues of praxis, peacemaking criminology is committed to policies including but not limited to: abolition of the death penalty; universal health care; economic redistribution; antidiscriminatory wage policies; drug decriminalization; the replacement of adversarial criminal justice practices with peacemaking mediation (for further discussion, see Sullivan and Tifft, 1998).

Restorative Justice and Social Justice

Restorative justice is an approach of responding to crime that emphasizes repairing the harms caused by criminal acts by way of offender accountability, victim needs, and meaningful change at micro-, mezzo-, and/or macrolevels. This is accomplished by bringing together offenders, victims, and others impacted by criminal act(s) in an effort to cooperatively achieve a just response to a criminal harm. Including victims, offenders, and other community stakeholders in the response to crime, acts to empower the individuals most impacted by the criminal harm. The shared power dynamic illustrates the influence of social justice on restorative justice ideologies. Furthermore, restorative justice approaches promote empathy by design, and aim to be nonadversarial. Many criminologists are acquainted with the term restorative justice via the work of John Braithwaite, and his reintegrative shaming theory.

Restorative justice has inspired a number of policy initiatives, especially directives concerning juveniles and delinquency. For example, the Office of Juvenile Justice and Delinquency Prevention lists and describes five different examples of commonly employed juvenile justice programs associated with restorative justice (Office of Juvenile Justice and Delinquency Prevention, 2013). These initiatives include family group conferences, victim–impact panels, victim–offender mediation, circle sentencing, and community reparative boards. While each of these programs are inspired by the same underlying restorative justice principals, they vary with respect to implementation and practice. For example, family group conferences, victim–offender mediation, and circle sentencing traditionally bring together the victim and offender in person. Victim–impact panels bring together offenders, and persons who have been victimized by similar crimes as those carried out by the offender, or in some cases, secondary victims of the offender's crime are present. Community reparative boards bring together offenders and a trained board of community members who mutually determine sanctions.

In recent years, researchers and practitioners have suggested restorative justice initiatives as an alternative to more punitive or zero-tolerance school disciplinary policies (Morrison and Vaandering, 2012; Nickerson and Spears, 2007). Zero-tolerance school disciplinary policies refer to harsh, draconian school disciplinary practices inspired by the 1990s 'tough on crime' movement, and moral panic surrounding highly publicized school shooting incidents. These policies have been criticized as discriminatory, racist, and a contributing force to the recently termed "School to Prison Pipeline" (Kim et al., 2010). The use of restorative approaches to school discipline, including mental health services, counseling, and other reintegrative initiatives, have been advocated as preferable to suspensions, expulsions, and justice system referrals (Nickerson and Spears, 2007).

Victim Advocacy and Social Justice

Crime victims represent a particularly vulnerable population for a number of reasons. For example, crime victims may endure damaged or lost property, inclusive of wages or earnings. In other instances, crime victims may suffer bodily harm or injury that threatens or changes their health and productivity. Crime victims may suffer emotional trauma, or even the loss of a friend or loved one. Because the damages of crime are associated with a number of these life-altering consequences, crime victims may no longer have access to resources in the same way as they had prior to their victimization. As such, a number of government and non-for-profit agencies have emerged to protect and assist those who have been victimized by crime. In this way, these agencies act to obtain or preserve social justice for crime victims.

Victim advocacy has emerged as one avenue by which crime victims' rights and access to resources are protected. For example, state victim advocacy boards provide compensation to crime victims to help offset medical expenses incurred from their victimization, seek counseling services, or retain an attorney. Government victim advocacy agencies also issue grants to providers that serve crime victims. Non-for-profit entities also advocate for crime victims. For example, the Salvation Army operates a nation-wide domestic violence and rape crisis program, inclusive of a toll free hotline. By serving victims in this way, these programs aim to optimize the health and functioning of crime victims, as it were prior to their victimization. By working to offset the harms imposed by crime, these programs can be understood as protecting social justice for crime victims.

Environmental Justice and Social Justice

For many years, clean air, soil, and drinking water was considered a basic human right, and under the domain of the public commons. However, following the Industrial Revolution, this has changed drastically, with means of production posing very severe and lasting impacts on public health and environmental sustainability. Over time, this has ultimately led to an unequal distribution of environmental hazards – such as industrial sites, toxins like mercury or lead, polluted drinking water – worldwide, leaving some communities more vulnerable to environmental hazards. Likewise, the same environmental 'goods' that were once part of the public commons – clean air, water, soil – now also appear to follow skewed distributions. Unequal access to clean air, water, and soil is interpreted by many as a threat to social justice.

In recent years, researchers and environmental activists have become interested in the nonrandom distributions of environmental 'goods' and 'bads.' In particular, some have

been captivated by the demographic composition of areas surrounding environmental goods and hazard sites. This field has come to be known as environmental justice, and concerns social justice in so far as the sociological processes that determine the distribution of environmental hazards. A number of studies have established that communities that house areas designated by the Environmental Protection Agency as in need of clean up tend to be areas of lower socioeconomic status and also have higher concentrations of minority residents (Saha and Mohai, 2005). Moreover, studies have also demonstrated that communities of higher socioeconomic status and higher concentrations of white residents tend to house desirable environmental properties (Landry and Chakraborty, 2009; Lynch and Stretesky, 2013). For example, a study conducted by Landry and Chakraborty (2009) found that communities of predominantly affluent, white, homeowners were more likely to contain trees in public spaces when compared to communities of predominately economically disadvantaged, black, renters. Lynch and Stretesky (2013) found an inverse relationship between density of citizen-led water-monitoring organizations, and percentage of ethnic and racial minority residents, net of confounders. Because environmental hazards can pose threats to public health and property values, environmental hazards can hinder or impair a person's access to resources. In this way, environmental justice is closely intertwined with social justice.

Public Health and Social Justice

Public health represents another realm that is impacted by social justice, and threatened by social inequalities. Consider that a number of factors that impact human health are decidedly social in nature. These factors include, though are not limited to the environment, access to quality medical services, access to preventive care, health insurance, and health education. To provide one of many examples of intersections between public health and social justice, consider disparities in diet and nutrition. The concept 'food desert' was coined to describe an area where limited access to affordable, healthy food options acts as a contributing factor to spatial and social disparities in health and diet (Beaulac et al., 2009). Studies in public health and urban ecology have documented disparities in the distribution of 'food deserts' across the United States with respect to race and class composition of neighborhoods (Beaulac et al., 2009; Gordon et al., 2011). A systematic review of the literature identifies 49 studies that examine the presence of food deserts in socioeconomically disadvantaged regions, and concludes that there is evidence that food access disparities with respect to race and class exist in the United States (Beaulac et al., 2009). Because of dynamics between races, socioeconomic status, and urban planning appear to interact with access to affordable, healthy foods, public health represents another domain of social justice issues.

Mental Health and Social Justice

Mental health is another domain that evinces social justice concerns. Even though mental health is typically understood as an individual trait, macrolevel patterns in psychological well-being have been observed across demographic groups. These relationships appear nuanced by specific disorder and demographic characteristic (Sheppard, 2002). For example, a positive correlation between economic status and mental health has been observed for decades (Bebbington et al., 2000; Hollingshead and Redlich, 1958). Studies have also demonstrated that women tend to be overrepresented among depression sufferers, while men tend to be overrepresented among schitzophrenics (Sheppard, 2002). In some cases, class has demonstrated to exacerbate race and gender associations with mental health: in one study, working-class women were observed as more likely to be depressed than middle-class women (Brown and Harris, 1978).

The intersections between social justice and mental health also have implications within the criminal justice system. For instance, emotional behavioral disorders tend to emerge at higher rates among inmates than within the general population. Reports from the Department of Justice suggest that nearly half of all inmates in state prisons report some symptoms of mental health disorders (James and Glaze, 2006). By comparison, other accounts suggest that among the general population, approximately 10% of persons report symptoms of mental health disorders (James and Glaze, 2006). One implication of the overrepresentation of mental health conditions among offending populations, is that correctional facilities have become *de facto* mental health service providers. Given diminishing budgets and the high stigmatization of mental health services, correctional facilities may represent the first or only opportunity for some persons to obtain help for mental health conditions. Moreover, as per the Holmes and Rahe (1967) Stress Scale, imprisonment in and of itself can act as a major contributor toward a stress-related mental health breakdown. Given the class biases and disproportionate minority contact that emerges throughout the justice system, combined with gender and ethnicity disparities, both mental health and incarceration share overlapping social justice concerns.

Social Work and Social Justice

The attainment and preservation of social justice has been described as a fundamental value of the social work discipline (Olson et al., 2013). Sheafor and Horejsi (2003) describe social justice as the fairness in the way the most powerful groups in society (governments, corporations) support and protect the basic human rights of all members of a society. To break down this definition further, Sheafor and Horejsi (2003) explain that, in general, the social work discipline recognizes basic, fundamental human rights of all persons. These rights include (though are not limited to) protection from abuse, a right to work and earn income to support oneself, and a right to quality education and health-care services. In addition, these rights operate independently of economic status or other personal achievements; rather, they are basic human rights afforded to members of a society simply by virtue of one's own existence. Because social work recognizes the importance of these basic human rights, social work also recognizes that societies have

a responsibility to protect basic human rights. That is, social work interprets rights and responsibilities as two sides of the same coin (Sheafor and Horejsi, 2003). For example, if people have the right to earn wages to support themselves, society has a responsibility to preserve fair and equal access to gainful employment.

One method that social institutions employ for protection of basic human rights is the criminal law. For this reason, there is considerable overlap between the mission of social work and the function of the criminal law and criminal justice system. For example, society recognizes a right to be free from abuse. Consequentially, laws exist to protect persons from physical harm and abuse. Agents of the criminal justice system have been granted the power to enforce these laws in the interest of protecting citizens from harm. Social workers have served as advocates for the creation of certain laws and social action (e.g., Etta Wheeler is recognized as a social worker who influenced social institutions to take an active role in protecting young people from child abuse), as well as intervening to protect human rights at individual and family levels. However, that society recognizes protections of some harms (e.g., acts of interpersonal violence) over others (e.g., injurious corporate crimes), remains a social justice concern for social workers and criminal justice researchers and practitioners alike (Reiman and Leighton, 2012).

Prison Abolition and Social Justice

According to Mayrl (2013) prison abolition represents a social justice issue that took root in the 1970s, but experienced renewed attention in the late 1990s. Prison abolitionists call for the outright elimination of prisons, and thereby an end to the use of prisons as a means of responding to social problems. Prison abolitionists do not interpret imprisonment as a meaningful or effective response to social ills (e.g., crime). Rather, prison abolitionists view imprisonment as a form of oppression, thereby acting as a mechanism that reproduces and reinforces social inequities. The term 'prison industrial complex' has been used to describe the intersections between the boom in the prison population, the emergence of private, for-profit prisons, and the manipulation of fear of crime by politicians and mainstream media. Parallel to Eisenhower's coining of the phrase "military industrial complex," used to describe the use and production of military arms to advance economic and political agendas, the prison industrial complex has been interpreted as advancing ulterior economic and political agendas (Mayrl, 2013). That is, the prison boom may be better explained as a lucrative business practice, or election campaign strategy, rather than an empirically justified approach to crime control. Because prison populations tend to be individuals of lower socioeconomic status, persons struggling with addiction and other mental health problems, as well as racial and ethnic minorities, prison abolitionists draw attention to the fact that prisons reinforce the marginalization of these minority groups. For these reasons, prison abolitionists interpret imprisonment as a form of oppression, and in turn, a threat to social justice.

Conclusion

In sum, social justice is a broad, interdisciplinary topic that continues to be particularly relevant to criminology. Social justice also continues to captivate practitioners and activists, some of which have galvanized to form influential social justice movements. Many of these movements organize and champion one or more specific social justice issue, and concentrate their efforts on heightening awareness and/or advocating for change. Examples of well-known social justice movements include the US civil rights movement, the women's suffrage movement, and more recently, the occupy wall street movement (Portland State University, 2013). These movements not only acted as powerful forces in shaping US civil rights and liberties, but also educate and inspire policy makers and grass roots social justice movements that continue to develop today.

Social Justice and Social Inequalities

Abstract

Social justice is a philosophical and transdisciplinary concept that has no particular or distinct disciplinary home. Social justice in theory and practice is part of the general evolution of justice in human civilizations, which is a part of the ongoing struggles against the repression of any people and on behalf of the liberation of all people. The applications of social justice are best understood in relation to the applications of equal justice and restorative justice.

Social justice is a philosophical and transdisciplinary concept that has no particular or distinct disciplinary home. Within and without the domains of criminology, both the struggle for and the study of social justice are underdeveloped and/or unfinished projects. Presently, the constitution of social justice and how to secure human rights for all are not firmly established or agreed upon by most people. Nevertheless, a listing of the basic liberties of social justice includes freedom of ideas, thoughts, and speech; freedom of association; freedom of ethnic and religious culture; freedom from slavery; freedom from racism, sexism, and discrimination; the right to equality and human needs for all; and the redistribution of power, wealth, and status for all, and for entire societies (Sadeghi and Price, 2007).

Over the short term, the struggle for social justice has reflected the historical changes and continuities that helped to form the Universal Declaration of Human Rights (UDHR), adopted by the General Assembly of the United Nations in 1948. Drawing on the battle cry of the French Revolution, 'dignity, liberty, equality, and brotherhood'; on the demands of the Industrial Revolution for political, social, and economic equity; and, finally, on the communal and national solidarity movements associated with the postcolonial era, the articles of the UDHR brought together in one document the universal meanings of human rights.

This struggle for universal human rights within the evolution of justice has not followed anything resembling a linear pathway forward in time and space. Not only has every generation of rights met with resistance, but also major strides on the course to human rights efficacy have also experienced some kind of backlash or setback. To be sure, reactionary forces have not typically nullified each progressive chapter in the acquisition of human rights. In fact, the collective evidence is otherwise: "History preserves the human rights record as each generation builds on the hopes and achievements of its predecessors while struggling to free itself from authoritarianism and improve its social conditions" for the future (Ishay, 2004: p. 4).

Background

Social justice may be thought of simply as "the common good through the equalization of goods or services" (Sadeghi and Price, 2007: p. 4), or it may be more elaborately defined as "the fair distribution of opportunities, rewards and responsibilities in society, as well as principles and institutions for the distribution of meaningful social goods – income, shelter, food, health, education, the freedom to pursue individual goals" (Hudson, 2013: p. 432).

An Italian Catholic priest, Luigi Taparelli, coined the term 'social justice.' In his book, *Theoretical Treatise on Natural Law* (published between 1840 and 1843), and based on the teachings of Thomas Aquinas, he claimed that the components of social justice were products of "natural theology, in which morality, based on religion, ought to be sought after by all people, who, under God, must adhere to their moral beliefs in doing what is right" (Sadeghi and Price, 2007: p. 699). In 1948, the late Father William J. Ferree (1997) in his "The Act of Social Justice" had characterized social justice as the duty in which each person in society is morally obligated to care for the common good of all.

Probably the most influential theory of social justice has been John Rawls' notion of "justice as fairness" in his *A Theory of Justice* (1972), which draws upon both the basic social contract theory and the Kantian philosophical tradition of justice as impartiality. Like most theorists on social justice, Rawls focused his concerns on answering two fundamental questions. "First, how the rules for a fair distribution of meaningful social goods can be determined; second, how much or how little inequality is permissible in a socially just society" (Hudson, 2013: p. 432). In response to the first question, Rawls answers that the rules and institutions of a just society can be obtained only by people acting in an unnatural position of ignorance of their own position, or behind a "veil of ignorance." Accordingly, he is suggesting that a fair distribution can only come about by establishing rules or procedures designed for the purposes of securing impartiality as much as possible. With respect to the question of inequality versus equality or to Rawls's "principle of difference," which maintains that social and economic inequalities are just to the extent that they benefit everyone.

In answering these questions, Rawls sought to strike a balance between equality and freedom. Alternative theories usually prioritize one or the other. For example, Marxist theories line up behind equality; libertarian and neoliberal theories line up behind freedom. A variant of welfare liberalism articulated by Michael Walzer in *Spheres of Justice* (1983) defends pluralism and equality, wherein he argues that diverse goods and services should have different degrees of social distribution on the basis of individual need.

On the 'Evolution of Justice': Equal, Restorative, and Social

Justice is an evolving phenomenon in its ideation, ideology, and implementation. As social constructions and ideal systems, justice discourses and practices cannot be separated from the modern evolution of law, justice, and society – or of what can be described as a three-tier revolution in just-ology or in the entitlement of all human beings to share the exact same formal rights as everybody else regardless of their class, race or ethnicity, gender, religious, national, or sexual affiliation (Ishay, 2004). When each of these models or systems of justice first emerged, they represented a particular stage in the struggle to expand individual rights in relation to both the collective rights of societies and the rights of the nation-states. Ultimately, these rights were extended to all peoples as universal human rights.

The first generation of rights represented the struggle for 'equal justice' or the struggle for 'negative rights.' These called for a restraint from uninhibited state or monarchial power over the individual. This generation of rights was derived from the American and French Revolutions, which both struggled to gain freedom from arbitrary rule. Collectively, these rights, articulated more recently in the Civil and Political Rights of the International Bill of Rights (1966), have shaped governmental control by "rule of law" rather than "rule of man." In the domains of crime and crime control, these rights have at least formally established an impartial and fair enforcement of the procedural and substantive components of the criminal and civil laws.

The second generation of rights represented the struggle for 'restorative justice' or the struggle for 'positive rights.' These called for 'affirmative' actions by and/or on behalf of the state for pursuing the common welfare. Rooted in the struggles to democratize governments and to make them responsible to the needs of people living in 'post' laissez-faire monopoly societies as a whole, these rights have shaped the sociopolitical obligations or minimal duties of the state to facilitate the self-actualization of individual human beings (Barak, 1980). These rights were also collectively articulated in 1966, in the Economic, Social, and Cultural Rights of the International Bill of Rights. In the domains of crime and crime prevention, these have included an emphasis on community social welfare, penitence and redemption, and offender–victim reconciliation.

The third generation of rights is represented by the contemporary worldwide struggle for 'social justice,' or the struggle for universal human rights. Evolving out of the emerging conditions of global interdependence, these rights call for international rules of interaction, such as the establishment of the International Criminal Court in The Hague in 1999. These universal rights also recognize that the delivery of negative and positive rights for all cannot be satisfied within the body of individual states acting alone. In the universal struggle for social justice, world peace, and victim reduction, global emphases have been on ending world hunger, forgiving debt to underdeveloped nations, and treating victims of AIDS/HIV and other debilitating and/or life-threatening diseases, famines, tsunamis, and so forth worldwide.

Equal Justice

In most developed nations like the United States, equal justice assumes the rationality of the prevailing political, economic, and social arrangements in general and of the administration of criminal justice in particular. Within those systems of justice, where criminals are viewed as 'bad' and 'mad,' they are typically disconnected from their social conditions and from their class, racial or ethnic, gendered, and sexual relations. Whether defendants are from at-risk social environments or from privileged milieus, these facts are not formally relevant to the accused or convicted offenders as all are subject to the same 'equal justice' or due process of the law.

Ignoring the effects of social structures and ecologies of crime, these models of equal justice have traditionally not considered the interests of either the injured parties or their perpetrators or the communities from which they originate. Furthermore, the policies of equal justice do not take into account the concept of equal sanctions for unequal offenders or victims. Similarly, the unequal treatment of analogous social injuries or harms perpetrated by the powerful and the powerless, respectively, serve to reproduce the status quo of crime, victimization, and discriminatory justice for many.

The contemporary model of equal justice practices in the United States has its roots in the mid-eighteenth century, when the European Age of Reason or Enlightenment was busy reforming the excessively arbitrary and barbaric justice practices from the medieval period. Although not driven by revenge or vengeance, these utilitarian and practical applications of equal-formal (retributive) justice are repressive as these help to perpetuate a class of marginally 'dangerous' offenders. At the same time, these policies of equal criminal justice downplay the value for most rule violators of flexible sentencing and community alternatives to imprisonment.

Restorative Justice

Fundamentally, restorative justice systems are about decentering punishment in regulatory institutions. At the same time, restorative justice acknowledges the place that punishment has as a means of communicating the 'shamefulness' of the acts in question (Braithwaite et al., 2006). Restorative policies and practices of justice assume that most offenders and nonoffenders, whether perpetrators, victims, or both, fundamentally share an intrinsic humanity (Zehr and Mika, 1998).

Modern practices of restorative justice have their legal roots in the ancient patterns of such diverse cultures as the Sumerian Code of UrNammu (2050 BC), the Hebrew Scriptures and the Code of Hammurabi (1700 BC), the Roman Law of the Twelve Tribes (449 BC), and the earliest collection of the Germanic tribal laws, the Lex Salica (AD 496). Each of these legal systems required that offenders and their families settle accounts with victims and their families, not simply to ensure that injured persons received restitution or compensation but also to ensure that communities were reestablished or restored to their former peace. Similarly, in many precolonial and indigenous societies around the world, sanctions were also primarily compensatory rather than retributive, intended primarily to make victims whole or to restore them to their previous status (Barak et al., 2010).

Restorative justice is being pursued when the focus of justice is on the harms of wrongdoing more than the rules that have been broken, and on the victims and offenders working toward the restoration of the former and the support of the latter in understanding their transgressions and meeting their obligations to make things right again; and is aimed at empowering those affected parties in the processes of justice and dialogue. For example, contemporary systems of Japanese justice, which emphasize 'confession, repentance, and absolution,' are about compensating their victims and restoring community peace (Van Ness and Heetderks-Strong, 1997).

Today, the idea of restorative justice has come to have many different meanings and practices. It has come to be associated with innovations in community mediation, problem-solving justice, victim–offender reconciliation, alternative sentencing, and community service (Daly and Immarigeon, 1998). Regardless of the myriad of practices that seem to be part of a larger movement to incorporate restorative justice programs into communities, they all share in common the desire to move beyond the illegality of the crime to the more fundamental needs of human dignity and respect as well as to the mediated sources of conflict and dispute resolution.

Unlike equal justice systems that revolve around how much pain and suffering have been inflicted by the actions of the wrongdoer, restorative justice systems revolve around how much harm has been repaired or will be prevented ('less harm'). Restorative justice systems are preoccupied with both the interpersonal and larger structural-mutualistic relationships involving offenders, victims, family members, and the neighborhoods from which they are spawned. More specifically, restorative justice emphasizes the recovery of the victim through the processes of redress, vindication, and healing, on the one hand, and of the offender through the processes of fair treatment, reformation, and recompense to the victim, on the other.

Finally, restorative justice relies on both the formal and informal mechanism of social control as it supports the role of government as being responsible for preserving law and order and the role of the community as being responsible for preserving peace and justice. Most importantly, for example, restorative justice involving victim–offender encounters or reconciliation programs tends to humanize both offenders and victims to the other and "permits them substantial creativity in constructing a response that deals not only with the injustice that occurred but with the futures of both parties as well" (Van Ness and Heetderks-Strong, 1997: p. 89).

Social Justice

While equal justice systems revolve primarily around retribution between the offender and the state, and restorative justice systems revolve primarily around reparation and healing between the offender and the victim, social justice systems venture beyond immediate conflicts – perpetrators, victims, and communities – to an account of larger political, economic, and social arrangements. Social justice models incorporate, for example, patterns of social inequality or disadvantage as well as patterns of privilege, power, and advantage, which make people and their communities susceptible or not to the experiences of criminal harm and to the processes of criminalization.

The visions of equity and fairness associated with the policies of social justice are broader and more ambitious than those visions associated with the models of equal and restorative justice. Social justice models expand the notions of conflict and injury beyond what the sovereign law recognizes to include those harms identified as part of an evolving set of human rights, some established in treaties and covenants, and some in international resolutions or tribunals. The violations of any of these fundamental rights constitute what are known in the world community as 'crimes against humanity.'

These offenses generally are committed by policies or practices or by the authorities or agents of the state, such as in the violation of a person and/or a group's inalienable rights to be free, for example, from exploitation, slavery, impoverishment, hatred, discrimination, or genocide. In this context, social justice recognizes harms, injuries, offenses, wrongs, crimes, and violations that are not merely expressions of interpersonal conflict but also expressions of the organizational, institutional, and structural relations of the prevailing political, economic, and social arrangements. Accordingly, to address the underpinning structural inequities or injustices in those arrangements, social justice stresses the importance of public policies of 'harm reduction' that go beyond the confines of the criminal justice system.

Therefore, attention is paid not only to the obvious crimes of the powerful, such as those committed in corporate America or on Wall Street, but also more generally to the economic harm and social victimization caused by all types of deregulation, from environmental to financial; to the lack of social and human capital formation; and to the oppression and exploitation of a growing multiethnic underclass in the United States and many other nations. To the extent that these social forces create crime and crime control systems, in the forms of equal or restorative justice, which are repressive in the sense that they secure a legal order that reinforces inequality and privilege, social justice models advocate a 'war' or intervention against those forces.

In the evolution of justice, what distinguishes social justice from equal justice and restorative justice is that only the former model of justice struggles to escape the confines or shackles of bourgeois legality. The problems with capitalist Constitutions like the United States' are the many claims that equal rights and responsibilities have been substituted for the harsh realities of class domination. In other words, by way of the Constitution, the struggle over the legitimacy of social acts is removed from the plane of morality and society. In turn, these social actions or relationships are relocated in the plane of law and politics. Justice is no longer what is fair but what is legal and politically expedient as decided mostly by lawyers and judges playing by the capitalist rules of the game (Ollman, 1987).

Ultimately, to overcome class domination and/or to achieve social justice, the political economies and societies of the world will have to transition from capitalist formations to socialist formations. Otherwise, social justice for all will remain an unrealized 'pipe dream' trapped in the realities or contradictions of capitalist inequalities. In the meantime, piecemeal or halfhearted reforms in the name of social justice are resumed and advanced.

For example, some proponents of social justice advocate on behalf of 'visionary gradualism' or 'free-market socialism' (Harrington, 1989). Other social justice proponents talk in terms

of democratizing and humanizing capitalism (Shiller, 2011). Grounded in the global principles of feminist, antiracial, and ecological justice, these views still ascribe to the political economies of capitalism. At the same time, these 'social justicians' believe in the eradication of social subjugation, oppression, and exploitation as well as in the establishment of fundamental human rights for all. They oppose unenlightened self-interest, unregulated markets, and unfettered victimization (Barak, 2012).

The Limitations of Equal Justice and the Struggle for Sovereign Justice

As Anatole France wrote about the inefficacy of equal justice in his best-selling *The Red Lily* in 1894, "The law, in its majestic equality, forbids rich and poor to sleep under bridges, to beg in the streets, and to steal bread" (quoted in Sadeghi and Price, 2007: p. 699). Then and now, such laws as those are naturally only relevant to the marginal, to the destitute, to the homeless, to the mentally ill, and so on. Hence, when legal evaluations or assessments of justice – criminal or civil – ignore differences of class, ethnicity, gender, or sexuality in particular and socioeconomic statuses in general, or when they falsely treat unequal persons or corporations under the law as one and the same, they 'blindly' reinforce these differences or inequalities.

Similarly, because of an ideological preference for bourgeois legality with its overemphasis on notions of individual-equal justice, most critiques of the administration of justice fall short. Instead of focusing on the substantive inadequacies of the criminalizing and penalizing processes and the selective and differential outcomes that systemically hurt the powerless and benefit the powerful, most critiques focus on procedural irregularities or on applications of due process and equal protection under the law. The point is that there is a long list of harms and injuries that have been and/or could be prohibited by law that victimize millions of people daily, yet are commonly treated by the legal order as if these actions or omissions were or are 'beyond incrimination' (Barak, 1991a, 1991b, 2012).

Moreover, the consequences of these selective enforcements, differential applications, and inauspicious omissions are counterproductive not only for alleviating pain or reducing harm, but also for obtaining social justice for the most marginalized members of society. For example, the unsuccessful policies of the 'war on drugs,' mandatory sentencing, and the widening of the nets of crime control on less serious offenders have adversely affected African American families and, to a lesser extent, Latino American families. In the case of the former, the large-scale removal of young black males from their communities has contributed to the depletion of the supply of potential marriage partners for young black females and to the accumulation of generational impoverishment. Some criminologists have argued that these social relations of crime, victimization, and punishment have encouraged young female-headed households, creating precisely the types of family formations that have been linked with higher rates of street crime and domestic abuse when not given adequate social support (Currie, 2005; Messner and Rosenfeld, 1994; Foster and Hagan, 2009).

In turn, these countereffective policies coupled with assembly-line, plea-bargained, and bureaucratized equal justice for the marginal classes help to reinforce stereotypic images of criminals. These exclude high-powered corporate executives, emphasizing low-life predators who murder, rob, assault, kidnap, and do drugs rather than white-collar looters who inside trade, contract without bidding, or commit high-stakes securities fraud. To be clear, the point of this critique is not to argue against equal justice in the administration of laws. It is to argue against equal justice as the endpoint of justice rather than as a means to complementing other systems of justice. Indeed, all agents or workers of the various equal justice systems should aspire to act impartially or neutrally, according to both the letter and the spirit of due process and equal protection under the law. However, to achieve social justice, legal-equal justice represents the most elementary of steps.

In addition, equal justice needs to be assisted by the goals and objectives of restorative and social justice if the mass victimization of peoples around the world is to decline. These latter models of justice offer substantial ways to improve the quality of justice beyond the existing legal processes, helping to better curb and reduce all forms of harm and injury – personal, organizational, institutional, and structural – than equal justice systems do.

The Limitations of International Law and the Struggle for Global Justice

The contradictions in the spirit and the enforcement of international law inhibit a reduction in both the worldwide victimization of people and the reproduction of crime and violence. This is because international law does not facilitate the ability of the global community to satisfy the basic human needs and rights of all people. At its core:

> International law is a limitation on autonomy, yet one that has its maximal force when other states are willing to act in its name. The twentieth and twenty-first centuries have shown that when states elect to act 'in the name' of international law… they often do so (or refuse to do so) out of their own political and economic interests rather than within the interests of an international social order. (Mullin and Rothe, 2008: p. 26)

The radical vision of social justice shared below stems from a humanistic, democratic, and participatory world order based on 'mixed' economies of public and private ownership, where people cooperate in both the work and leisure of their local and global communities. It is not that societies will have removed their economic and other forms of competition. Rather, these reciprocal interactions of capital and labor will work on the premises of 'fair' rather than 'free' exchanges of goods and services. These social relations are also underpinned by sustainable and balanced ecosystems. A global order of this kind strives for ecological harmony in the context of climate change and in the ways in which societies and technologies interact with their natural environments to protect all forms of life and habitat (Barak, 2009).

Human Needs

At the beginning of the twenty-first century, we live in a world of shrinking resources but not in a world of scarcity of goods and services. Thus, in a world organized around ecological sustainability, a primary goal of global production of international economic activity should be for the provision of the necessities of life for all of earth's inhabitants. These basics should include but not be limited to food, shelter, healthcare, childcare, education, social services, culture, art, leisure, recreation, work, peace, and security. In brief, this is social production for use and profit by all so that whole groups of people do not have to needlessly suffer.

Human Rights

The objective here is to maximize and extend civil and human rights for all people, which means also curbing abuses and discriminatory actions based on or stemming from differences due to age, ethnicity, gender, sexual orientation, religious affiliation, disability, or migratory status. For example, with regard to sexual orientation, the end of all anti-gay, lesbian, bisexual, and transgender restrictions in the law; or, concerning age, there are special rights that may be attached to children and seniors; regarding women, the reduction and elimination of all forms of sexism, especially that which revolves around sexual harassment, violence, and exploitation; and finally, concerning migratory workers, a global world order that would recognize the rights of people to freely move across borders to live, visit, and work as they choose.

Human Justness

Perhaps the toughest struggles for social justice have to do with obtaining human justness *in* everyday or ordinary public-private contracts, and *for* exceptional or extraordinary atrocities. In the case of the former, do the ways in which contracts or 'right-to-work' laws are written adversely affect workers in general, and current or former inmates in relation to the penal-industrial complex in particular? In the case of the latter, there are the largely inadequate or unresponsive actions to acts of genocidal rape or to other crimes against humanity, such as torture. With domestic and international laws in place to challenge these various forms of harms and social injuries, there is hope that such behavior might be reduced, if not deferred, altogether. Without either changing the fundamental international motivations and opportunities of a global economy and/or establishing the necessary constraints and customary controls to curb these types of antisocial behavior, however, governments and their proxies in specific situations are under little or no pressure to refrain from their continued abuse.

Future Prospects

Dialectically, within an 'evolving' system of social justice and a developing system of capitalism worldwide, there are presently more middle classes emerging than there are middle classes disappearing. At the same time, as the wealth gap expands and inequality accelerates, the competition for uneven wage differences intensifies at home and abroad. Meanwhile, the hegemonic neoliberal policies – austerity, privatization, and deregulation – that are directing both domestic and international development all work against the materialization of redistributing the wealth for all human beings. In addition to expanding or widening the universality of humanitarian law and practice, the struggle for social justice has to consolidate its effort, nationally and supranationally, to resist those harmful policies of hierarchy and privilege. The struggle for social justice should also devise alternative strategies for democratizing and humanizing the vagaries of capitalism.

Abstract

Social justice, generally considered a type or subcategory of justice, has been variously defined. Some authors consider it equivalent to 'distributive justice' while others differentiate it from both general justice and distributive justice. In the latter approach, social justice is seen as a unique type of justice characterized by a focus on the 'common good' and the individual's obligation and right to make a contribution to that (hence, sometimes called 'contributive' justice) while acknowledging the role of the state and civil society to remove barriers that prevent individuals from so doing. Defining it theoretically and determining how it can be advanced empirically, as well as questioning its usefulness in both arenas, are the focus of much contemporary attention.

Theories of Social Justice

While the concept of 'justice' has been around since at least the time of Plato, the term 'social justice' itself did not enter the lexicon until the mid-nineteenth century, through the writing of the conservative Italian Jesuit Luigi Taparelli d'Azeglio (Burke, 2008). Scholars in the Catholic intellectual tradition built on the foundational work about justice in the writings of Thomas Aquinas (who, in turn, built on the work of Aristotle); the link between justice and the 'common good', while complex, is pivotal in this tradition. There are some early twentieth-century attempts to explore the medieval roots of the modern understanding of the idea of social justice as well as to advance the thinking about the concept. The study of the general concept of justice, however, suffered hard times with the turn in philosophy to such approaches as analytic philosophy and logical positivism.

It is in the latter half of the twentieth century that we find renewed interest in theorizing about justice itself. Credit is given especially to the pioneering work of John Rawls for reviving that interest, and with scholars such as David Miller, Iris Marion Young, Amartya Sen, and Martha Nussbaum for extending it, particularly in a more explicitly social vein. Miller (1999) contends that what is involved in social justice is really the distribution of the good and bad things in life, as well as the question of how they should be distributed, thus making social justice an 'aspect' of or equivalent to distributive justice.

Young (2000) is more explicit in establishing social justice as its own concept. She does so by introducing what she calls 'two ideals of social justice', namely, self-development and self-determination, which correspond to two 'general conditions of injustice', namely, oppression (institutional constraint on self-development) and domination (institutional constraint on self-determination). This leads to her definition of social justice as "the institutional conditions for promoting self-development and self-determination of a society's members" (Young, 2000: p. 33). Why this is important is because of what Young claims is the 'goal' of social justice, namely, 'social equality', and here equality should be seen as "the full participation and inclusion of everyone in a society's major institutions, and the socially supported substantive opportunity for all to develop and exercise their capacities and realize their choices" (Young, 1990: p. 173).

Young is building on Rawls, who argues that the main subject of justice is the 'basic structure of society', meaning the arrangement of the major social and political institutions. Young (Young, 2011: p. 70) finds this approach inadequate, however, because Rawls "is looking for a *part* of the society, a small subset of its institutions that is more fundamental than other parts" (Young, 2011: p. 70, italics in original). She contends, however, that "Social structures are not a part of the society; instead they involve, or become visible in, a certain *way of looking* at the whole society, one that sees patterns in relations among people and the positions they occupy relative to one another"(Young, 2011: p. 70; italics in original). This brings Young's approach more in alignment with a fairly standard perspective from the social sciences, where social structure is seen as the relatively stable patterns of social relationships that both emerge from and constrain the actions of individuals, who occupy different and differentiated positions that have particular roles. However defined, issues of agency, access, norms, and power come to the fore as do levels of analysis such as individual-to-individual, intergroup, intrastate, interstate, and global.

The discussion of social structure is rooted, either implicitly or explicitly, in ideas about the human person or more generally about human nature. This in turn leads to ideas about what humans need, desire, and deserve. In his discussion of what persons need, Rawls refers to citizens 'who are fully cooperating members of society' (Rawls, 2001: p. 58). He puts forth the idea of 'primary goods' and distinguishes five kinds: basic rights and liberties; freedom of movement and free choice of occupation; powers and prerogatives of offices and positions of authority and responsibility; income and wealth; and the social bases of self-respect (Rawls, 2001: pp. 58–59). A concrete and comparative perspective is introduced by Sen (2004), who proposed that a 'capability approach' provides a tool for making comparisons about the quality of life of people in different nations. This approach led to the issuance of the 'Human Development Report', which first appeared in 1990, and eventually to the 'Human Development Index', introduced on the twentieth anniversary of that inaugural report. While

Nussbaum states that the capability approach was an attempt to alter the development and policy work, rather than to develop a theory of justice, she (Nussbaum, 2011: p. 18) has developed the idea, preferring to use the plural of capability. The resulting 'capabilities' approach "can be provisionally defined as an approach to comparative quality-of-life assessment and to theorizing about basic social justice" (Nussbaum, 2011: p. 18). In current scholarship, Corning (2011: p. 11) has been perhaps the most explicit about basic needs, arguing that there is a 'science' of human nature which tells us "that each of us is defined, in considerable measure, by an array of 'basic needs' that are essential to our survival and reproductive success, and we come into the world with an orientation toward satisfying these needs" of which there are no fewer than 14 'primary needs'. From that Corning (2011: p. 153) argues that we have the wherewithal to construct a new social contract, namely, a 'biosocial contract'. While clearly a normative theory, it is one built on an empirical foundation, he argues, that demonstrates that humans have an 'innate' sense of fairness that can be advanced through economic and political reforms. Criticism of Corning's approach rests in part on the contention it is a manifestation of the naturalistic fallacy and is basically an essentialist proposition.

The discussion of social structure, human nature, and basic needs brings to the fore two other related issues, the first dealing with opportunity and outcomes, and the second with participation. Regarding opportunity and social justice, the distinction often drawn is between equality of opportunity and equality of outcomes. To understand why some might prefer the former in conceptualizing social justice, we must take into account both the historical context under examination as well as the various cultural values in play. If one is attracted to the individualism tradition in the United States in the early twenty-first century, for example, the leaning might be more toward equality of opportunity. Assuming that the playing field can, in fact, be made level, then, some would argue, equality of opportunity fulfills the extent of the societal obligation to the conditions of social justice; it is up to the individual to do the rest. If, on the other hand, one is more inclined to a communitarian tradition, one might be predisposed to favor the equality of outcomes, believing that the playing field cannot be made level; the historical contingencies are so powerful at this point that some individuals and particular groups, on their own, simply cannot meet their basic needs and contribute to the common good.

This leads fairly readily to the second issue, namely, the concern with 'participation' in the conceptualization of social justice. As noted above, in at least one tradition participation is considered a *sine qua non* of social justice making it distinct from distributive justice. Young's writings, for example, seem to put her in line with this tradition (see also Craig, 2007). Separating out participation from the concept of distributive justice confronts the issue that distributive justice can be seen to imply an exclusive top-down or formal authority perspective: who or what 'decides' (according to whatever laws and policies) to distribute the benefits and burdens to the members of a society? With that approach, the notion of agency tends to redound to the state or societal level, hence either eliminating or at least minimizing the active involvement of individuals and groups to meet their basic needs and contribute to the larger society. While Miller (1999: p. 11) cautions against taking 'distributed' too literally, a case can be made that the argument for making social justice its own category is, at least in part, to emphasize the importance of individual and group agency while not excluding the key role of civil society and the state.

No discussion of social justice can avoid the topic of the role of the state. One basic view is that the state is ultimately responsible for creating and/or maintaining the structures and processes for allocating benefits and burdens in its geographic territory and supporting (or at least not undermining) an environment in which civil society and both individual and group action can flourish. Here the issue of citizenship calls for attention. Rawls (2001) situated his work in the context of a democratic society and spoke about the idea of citizens as free and equal persons in a well-ordered society. While acknowledging the complexities of state boundaries, types, and history, Miller (2003: p. 362) affirms his earlier claim that nations are a special form of community, which, in turn, 'gives the practice of justice among fellow nationals a certain kind of primacy'. And he is quite clear on the importance of paying attention to the beliefs of citizens when theorizing about the nature of social justice. Various critiques have been waged against the idea of social justice being confined to the boundaries of the state (Bell and de-Shalit, 2003). Part of the critique comes from examining the contemporary importance of the economy and the whole discussion of globalization and its implications both for the state as an actor and for the practice of social justice. Several points are worth noting here. One is the formidable challenge that arises if the idea of social justice is broadened to be inclusive of the entire global community. What entity takes on a coordinating, if not a dominating, role in advancing social justice and with what authority? How can social justice be the 'same' in each nation-state (or smaller political entity)? A second, which some would argue is so prevalent in each state that it behooves us to address this deep fissure before attempting to address global social justice, is the issue of the gendered division of society broadly speaking and of labor in particular. At one level, this can be seen as a concrete manifestation of the issue of equality of opportunity and equality of outcomes. An early critic of Rawls' theory in terms of the gendered division of labor is Susan Moller Okin (1987: p. 68), who finds Rawls 'original position' lacking: "if those in the original position did not know whether they were to be men or women, they would surely be concerned to establish a thoroughgoing social and economic equality between the sexes that would preserve either from the need to pander to or servilely provide for the pleasure of the other." Current discussions of 'gender mainstreaming' as a strategy to achieve gender equality (United Nations) and explorations of the roots of gender inequalities in the global economy (Reilly, 2009; Perrons, 2009) add to this concern.

Advancing Social Justice from the Local to Global/ Empirical Research on Social Justice

Understanding and advancing social justice, however it is defined, have occupied scholars and activists alike. Writers in such fields as law (Rand, 2006), clinical practice (Aldarondo, 2007), and public policy (Craig et al., 2008) have

contributed to the discussion as have many scholars in social science disciplines (e.g., Cohen, 1986; Feagin and Vera, 2008; Scherer, 1992). What has oftentimes motivated both scholars and activists in this work is to seek answers to the question: why is there so much human pain and suffering of so many people in the world and what can be done about it? If people believe that the pain and suffering of others is due to luck or chance or to their own actions, on the one hand, no obligation is felt to do something to alleviate their situation. But if people determine that the suffering is 'unjust', on the other, that "implies that we acknowledge the circumstance as grounded at least partly in institutions and the social processes they generate" and "we thereby at least implicitly recognize an obligation to try to improve those social processes" (Young, 2011: p. 33). So even to those seeking greater social justice and finding themselves in the latter category, the question remains: how can this be done? The topic of 'structural injustice' (Young, 2011) or 'structural violence' (Maas Weigert, 2008) is relevant to this discussion; the basic point of these concepts is to indicate that such injustice or structural violence is 'preventable'. In conceiving of social injustice as embedded in multiple policies, private and public social structures, and the actions of a myriad array of individuals, it is still the case that the challenges to discern ways to address that harm remain complicated and both historically and culturally contingent. Designing new policies, creating new structures, and fostering new practices are never easy and always involve contending viewpoints that must be acknowledged as new ways are sought. A perennial worry arises: there will be unintended consequences.

Some theorists and activists argue that it is only through nonviolent action at all levels that positive social change can occur with the hope of at least not making the situation worse and, more proactively, of actually advancing social justice. The work on nonviolent action has developed greatly since the mid-twentieth century and both the theoretical and empirical research on social movements are central to that conversation. An underlying point about nonviolent action is that such action is rooted in the power of the people. Refusing to obey is the beginning of the challenge to the authorities, be they the state or some other entity. That idea of popular support or lack thereof is, of course, central to democratic theorizing. Whether nonviolent withdrawal of support is conceived of as 'pragmatic' or 'principled', it is argued that nonviolent action is the better (if not, only) way to bring about a society that is characterized by greater social justice in processes and structures (see Sharp, 1973). Social movements, of course, can be 'conservative' or 'progressive'. Some believe, for example, that the current structures and processes are, in fact, the most appropriate for bringing about greater social justice; there is nothing 'inherent' in a social movement that says it is or must be 'progressive'.

Future Possibilities for the Concept and Practice of Social Justice

What is the future for the concept and practice of social justice? One challenge is the question of the very usefulness of the concept itself. Does not 'distributive justice' suffice to incorporate what some are trying to claim are key elements that define 'social' justice? Since so many writers seem to equate distributive and social justice, does it help or hinder the theorizing and research to draw a sharp distinction between the two? Those who oppose such combining might argue that the very term 'social' raises more clearly such essential topics as participation, agency, access, and power, and legitimizes those topics as central, not peripheral, to the discussion of social justice. A related concern is the question of content: what can be/must be/should be included in a definition of social justice? If anyone can use the term for whatever particular purposes, does that not weaken the concept itself? Of particular concern: if it is simply identified with the liberal/progressive agenda, does that not defeat or preclude rigorous theorizing and grounded empirical research? Some present an argument that supports the continued use of the concept but contend that the changes in the late twentieth and early twenty-first centuries demand a rethinking of the elements of social justice (Craig, 2007; Cramme and Diamond, 2009).

A second challenge deals with boundary issues. As noted above, Miller (1999: pp. 18–19) has argued that the nation-state has 'a special standing', one where its citizens 'share a common national identity' that results in a political community with three features making 'the application of principles of justice feasible and fruitful': (1) strong bonds of solidarity; (2) a range of shared understandings (regarding principles of desert and of need); and (3) trust backed up by compulsion guiding behavior. Thus he contends social justice is best conceived as applying within national political communities and, therefore, we need to 'understand global justice differently'.

How can the terms social justice and global justice be differentiated? Pitting them against each other does not seem fruitful. Yet it must be acknowledged that they may conflict and in such situations there will be a call for trade-offs (Cramme and Diamond, 2009; Miller, 2009). Determining when and under what conditions trade-offs might be called for is an important task. That, in turn, raises two issues: first, the issue of sovereignty and the nation-state. Is it the case that "the heyday of the nation-state is irrefutably at an end" (Cramme and Diamond, 2009: p. 4)? And if so, what does that mean for social and/or global justice? Second, if the answer to the first question is yes, two related questions emerge: what does the nation-state look like and how does it function in this transition or twilight period (Gautney et al., 2009)? How can a transnational system of governance be created "which complements national authorities in delivering the services and public goods that citizens need to enjoy opportunity and security" (Cramme and Diamond, 2009: p. 14)?

Rather than defining the terms, some social scientists approach the issues through research on particular problems and/or organizing cross-nationally. Banerjee and Duflo (2011), for example, offer research based on randomized control trials to determine what interventions actually 'work' or help in alleviating global poverty. Others are trying to create networks that enable people to work collaboratively in an effort to advance a new vision of 'global social justice'. In the claim of the World Social Forum, for example, 'another world is possible'. In recent years, ideas about 'struggle', 'suffering', and 'solidarity' are drawing explicit attention from such scholars as Feagin and Vera (2008) and Young (2011), as do questions about why people join social movements, locally and globally.

Global movements, around such concerns as climate change and aging societies, are now possible in new ways because the electronic world allows for connections not previously available, even though such means can also be used for greater concentration of power and the diminishment of a practice of greater social justice (Gautney et al., 2009). An example of a platform for connecting social scientists interested in social justice is The Sociological Think Tank, dedicated to "reflection and discussion among sociologists, other social scientists, students, activists, journalists and others who aim to promote human rights, equality, and global and local justice."

New methods and research address nations' capacities to alter the current situations as seen, for example, in the work on 'Sustainable Governance Indicators' by Bertelsmann Stiftung. The World Values Survey, organized as a global network of social scientists and coordinated by the World Values Survey Association, conducts surveys that address worldwide socio-cultural and political change. The aspiration for a more just, sustainable, and humane world finds some support in global data from that survey along with that from the Pew Research Center's Global Attitudes Project, where, for example, one finding is a global concern for growing economic inequality, with most people agreeing that the economic system favors the wealthy, data that address Miller's concern for consulting ordinary citizens in developing theories of social justice. Whether and how such research and networking can ultimately support greater theorizing about, and the advancing of, social justice remains to be seen.

Social Learning and Culture in Nonhuman Organisms

Rachel L Kendal, Durham University, Durham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article reviews the field of animal social learning and culture, covering how and why it is studied in both captive and wild animals, by researchers with often differing agendas. Our increasing understanding of the adaptive value of social learning and culture is discussed as well as the new avenues for research this opens. The interdisciplinary nature of the field is emphasized, which, among other areas, influences theories regarding modularity in the brain, the evolution of social intelligence, and animal conservation and welfare.

Whether or not nonhuman animals can be said to have 'culture' is a contentious issue that hangs on the definitions of culture and the complexities of animal social behavior. However, it is well established that numerous species have the ability to acquire from others skills, calls, and information concerning predators, mates, or resources. In some instances, this information transmission is sufficient to propagate the diffusion of novel behavior patterns through animal populations and to maintain distinct behavioral traditions between different populations of the same species. These traditions are sometimes regarded as analogous to human culture in many respects and have been described as culture. However, the use of this term indicates little more than that the behavior concerned has been learned socially and does not necessarily imply that the animals concerned are unusually intelligent, or that they have exceptional linguistic or cognitive capabilities.

Social Learning in Animals

Underlying culture in nonhuman animals is a capacity for 'social learning.' The term social learning refers to learning that is influenced by observation of, or interaction with, another animal (typically of the same species) or its products. Although social learning, as an umbrella term, may include active teaching (Hoppitt et al., 2008) or explicit communication, researchers of nonhumans usually mean no more by the term than the acquisition of information from others who inadvertently emit it while going about their business. Social learning is frequently contrasted with individual learning (also known as asocial learning, trial-and-error learning, and innovation), in which animals learn exclusively on the basis of their own experience, without recourse to social cues or guidance. In any instantiation of social learning, the learner or receiver of information is generally described as the 'observer,' whereas the transmitter of information is called the 'demonstrator.' Social learning occurs when the transmission of information between two animals results in the observer learning from the demonstrator. Frequently, the observer learns through social interaction to perform the same behavior as that exhibited by the demonstrator and, if repeated among other animals, this process can result in the spread of a particular behavior pattern and behavioral homogeneity in a population. Less frequently, animals may learn by observation to perform a different behavior from that exhibited by the demonstrator.

Social learning among animals has been of interest to scientists from a number of different disciplines. Psychologists traditionally have been interested in animal learning. Contemporary animal learning theory describes learning in animals according to three types of experience that cause a change in behavior: exposure to a single stimulus (stimulus (S) learning, e.g., habituation or sensitization); to an association between two external stimuli (stimulus–stimulus (S–S) or classical conditioning); or to an association between an external stimulus and an animal's behavioral response (stimulus–response (S–R), response–reinforcer (R–S) learning, or operant/instrumental conditioning). Arguments abound as to whether there is anything different or special about social, compared with asocial learning, and whether social learning can be adequately explained in conditioning terms. However, recent evidence does indicate that social and asocial learning depend upon the same learning mechanisms (reviewed by Heyes, 2011), rather than the alternative, that social learning is dependent upon a set of special-purpose modules evolved many times in different taxonomic groups as adaptive specializations for group living. This evidence includes findings that social learning and asocial learning covary. In birds and primates, social and asocial learning abilities are correlated positively across species even when accounting for differences in body mass, brain volume, phylogeny, and research effort. Likewise, within zebra finches and pigeons, asocial and social learning is correlated. Social learning abilities have also been found in solitary species, the common octopus and red-footed tortoise, which would not be expected if social learning evolved independently to asocial learning, and in response to the selection pressures of social living. Finally, social learning has the same key features across diverse species, including humans. That is, across species, the main types of social learning occur under the same observable conditions as the three main types distinguished for asocial learning (see Section Laboratory Studies of Animal Social Learning). Thus, social and asocial learning depend upon the same learning mechanisms that are taxonomically general rather than specialized. Indeed, Heyes (2011) recently claimed that, at the cognitive level, all that is 'social about social learning' is the biasing or tuning of input mechanisms (perception, attention, and motivation) toward other agents, as the actual long-term encoding of information is mediated

by general learning mechanisms. Transmission biases (or social learning strategies, see Section The Adaptive Value of Animal Social Learning) may be viewed in this light as socially biased input mechanisms that privilege information received via a social versus asocial channel as well as via specific social channels.

Social learning has also been of interest to ethologists and behavioral ecologists because it seems to allow animals to learn about their environments rapidly and efficiently, without having to engage in potentially costly or hazardous learning trials, or expend considerable time and energy exploring the environment. Animals can learn which foods to eat, acquire food processing skills, learn to identify predators, learn which members of the opposite sex to mate with, or develop songs and calls by exploiting the knowledge base of more experienced conspecifics (Heyes and Galef, 1996; Zentall and Galef, 1988). Social learning can be regarded as a shortcut to learning about the environment, but may incur a cost if the acquired knowledge is inappropriate or outdated (Giraldeau et al., 2002). Evolutionary biologists, biological anthropologists, and archaeologists have also studied animal social learning because it is accorded a prominent role in the evolution of human culture. Although definitions of human culture vary, one central feature is the transmission of acquired information between individuals through social learning processes. Many researchers believe that an understanding of the ways in which social learning operates in animal populations will generate insights into the evolutionary roots of human culture (Laland and Galef, 2009). Social learning is regarded as pivotal to a number of social intelligence hypotheses, which maintain that the evolution of high intelligence or large brains was driven by a capacity for social learning and culture (Byrne and Whiten, 1988). Linked to such theories is the suggestion by many psychologists that more complex forms of social learning might be indicative of the animal concerned possessing unusual or sophisticated psychological capabilities (Heyes, 1994). For instance, it has been suggested that for an animal to accurately imitate the motor patterns of another animal it must be conscious, must be capable of taking the other animal's perspective, must be unusually intelligent, or must be capable of intentional action. Although such claims have been hotly disputed, social learning is inextricably linked to other factors believed pivotal in the evolution of humanity's sociocognitive niche (see Section Social Learning and Social Intelligence).

History of Research into Animal Social Learning

The study of social learning in animals dates back to Darwin and flourished as a result of attempts to demonstrate mental continuity between humans and animals in order to prove that humans had evolved. For many Victorian scientists, demonstrations of social (then termed 'imitative') learning in animals were seen as providing evidence of an evolutionary origin of the higher mental faculties of humans. Imitation was regarded as intermediate in psychological complexity between animal instinct and human reasoning (Boakes, 1984). The verb 'to ape' and the phrase 'monkey see monkey do' are manifestations of the then commonly held view that simian primates are frequent imitators of each other's behavior.

Numerous observations of imitative behavior in primates and other animals were reported in the late nineteenth century, but attempts to demonstrate imitation proved problematic. It became apparent that there are many processes that can result in two animals expressing similar behavior. Researchers began to realize that anecdotal stories concerning animals in uncontrolled environments would not provide satisfactory evidence to address this issue. In the first decades of the twentieth century, Edward Thorndike, a leading psychologist, attempted to introduce some scientific rigor into investigations by carrying out controlled experiments exploring imitation in cats, dogs, and monkeys (Galef, 1988). Thorndike's experiments led him to the controversial conclusion that there was no evidence that animals could 'from an act witnessed learn to do an act.' Out of the controversy there emerged two distinct research traditions in the study of social learning: a laboratory experimental tradition, dominated by experimental psychology, and a second tradition that carried out observations of natural populations of animals, dominated by ethologists and primatologists. The laboratory approach has focused on investigating the psychological mechanisms underlying social learning. In contrast, field studies have reported behavior patterns spreading through animal populations or cultural traditions. More recently, researchers developed experimental approaches to the study of the spread of learned information through animal populations, including transmission chain and diffusion studies (Laland et al., 1993; Whiten and Mesoudi, 2008). In addition, mathematical approaches have explored the conditions under which social learning is expected to evolve, and the evolutionary consequences of social learning. Finally, the field has recently seen a marrying of empirical and ethological approaches in the development of statistical methods enabling robust investigation of social learning in wild animals (reviewed in Kendal et al., 2010; see Galef, 1988 for more on the history of research into animal social learning.)

Laboratory Studies of Animal Social Learning

Modern laboratory experiments investigating social learning in animals commonly train animals (called demonstrators) to perform a target behavior (e.g., to push a lever to get a food reward), pair these demonstrators with untrained experimental subjects (called observers) that watch the demonstrator perform the behavior, and then test the observers alone to establish whether they have learned to perform the target behavior (Galef, 1988). Frequently, the rate at which the subjects learn to perform the behavior is compared with that of the control subjects, which have received different forms of observational experience. Such experiments have established that there are a number of ways that animals can learn socially, the variants reflecting the nature of the observer's learning and the type of information transmitted from demonstrator to observer. For instance, in the lever-pressing example, the observers might learn at an accelerated rate relative to controls (1) because they learned of the presence or significance of the lever, (2) because they learned of the presence of food, (3) because their observational experience allowed them to form an association between the depressed lever and the appearance of food, or (4) because they formed

an association between the action of pressing the lever and the appearance of food. In addition, there are other nonsocial learning processes that could result in an elevation in the observers' performance, for example, if observation changes the observer's motivational state.

Such experiments have engendered a fissioning of social learning phenomena, resulting in a multitude of terms to describe the different processes that can result in social learning and spawning a host of classificatory schemes. At present, there is only partial consensus over the terminology. One reason for the lack of progress in consensus is that early classifications stemmed from the goal of providing a list of mechanisms to be ruled out by researchers if they are to claim 'true' imitation (that is matching of specific motor patterns between observer and demonstrator). Thus, until recently, relatively little attention was paid to distinguishing among the many potential nonimitative processes. In addition, some terms are defined using criteria that are not directly observable (i.e., processes inside individuals such as 'goals' or 'intentionality') or that are not amenable to experimental manipulation in the laboratory.

Galef (1988) identified seven processes that could result in social learning, whereas in the most recent classification scheme by Hoppitt and Laland (2008), nine social learning processes are identified. Yet, other researchers may well add to this number of processes through further delineations. For simplicity sake, the scheme of Whiten and Ham (1992) is outlined in which four classes of social learning are distinguished, which can be mapped onto asocial learning mechanisms (Heyes, 1994). 'Stimulus enhancement' occurs when the observer learns from the demonstrator to which object or location its behavior should be oriented. Thus, observation of another individual exposes the observer to a single stimulus (S-learning) leading to a change in the observer's behavior. For instance, British birds learned to peck open milk bottles, regardless of their location, and drink the cream by having their attention drawn to milk bottles by other feeding birds (Hinde and Fisher, 1951). (The term 'local enhancement' is sometimes used to describe similar phenomena, whereby observers become more likely to visit or interact with objects at a particular location.) 'Observational conditioning' occurs when the observer learns to what circumstances a behavior should be a response. Thus, another individual's behavior exposes the observer to a relationship between two external stimuli (S–S learning), leading to a change in the observer's behavior. For example, infant rhesus monkeys learned to respond to the presence of a snake with fear and avoidance behavior through observations of the screams and avoidance behavior of adults when exposed to snakes (Mineka and Cook, 1988).

Third and fourth in Whiten and Ham's (1992) scheme were 'imitation' and 'goal emulation' which, unless functioning in disregard of the outcome for the demonstrator, fall under the broader term of observational learning. Observational learning occurs when the observer learns of a relationship between a behavior and its outcome (response–reinforcer R–S learning). Thus, another individual's behavior facilitates stimulus–response (S–R) learning resulting in a change in the observer's subsequent behavior. Within this class of social learning processes is imitation, which was said to occur when the observer learns from the demonstrator to perform a specific motor pattern in a particular context. For instance, orangutans had been reported to go through the motions of washing clothes following observation of human caretakers who were doing the laundry. More recently, we have seen further delineations such as 'contextual imitation' and 'production imitation' (Hoppitt and Laland, 2008), which take into account the novelty of the behavior copied, the accuracy of motor pattern replication, and sequence learning.

Whiten and Ham's (1992) final process was goal emulation, which referred to instances where the observer learns from the demonstrator the goal to pursue or the result that can be achieved. This definition is problematic in that is refers to the observer's understanding of the demonstration, which is unobservable to the experimenter. For example, juvenile chimpanzees that observed a stick being used to rake in out-of-reach food appeared to learn that the goal of the action was to gain food using a stick but developed their own means of doing so (Tomasello et al., 1987). More recently, the term goal emulation has been subsumed under the broader term 'emulation,' which generally refers to instances where the observer copies the results of a demonstrator's behavior rather than the actions themselves (Hoppitt and Laland, 2008). It is recognized that there are many ways in which this may be achieved including 'object movement reenactment' whereby observers recreate the movements of the objects manipulated by the demonstrator. For example, pigeons, chimpanzees, and children are able to solve a simple task when observing manipulandi that move as if by a ghost, with no agent visible (Hopper, 2010). Finally, 'affordance learning' whereby observers learn what can be done with an object/manipulandi is variously defined as emulation (Hopper, 2010) or observational conditioning (Hoppitt and Laland, 2008). It should be noted that more than one of these social learning processes, as well as asocial learning, may come into play in any single learning event. (See Hoppitt and Laland (2008) for additional information regarding evidence for the outlined social learning processes and several that have been omitted such as social enhancement of food preferences, response facilitation, and social facilitation.)

In general, there remains a lack of consensus as to whether any of the current classification schemes are comprehensive or whether each of a given classification's categories is mutually exclusive. The plethora of competing terms and usage reflect an ignorance of the biological basis of social learning. At present, there is little understanding of the genetic, neural, or physiological processes that underlie the processing of sensory information, the associationist or transformational organization of this information, and the production of motor patterns, during social learning. There has, however, been an increased understanding of the neural circuitry of imitation in recent years. The neural correlates of vocal imitation in song birds have been extensively studied for many years, but it was not until the discovery of 'mirror neurons' in macaque monkeys (Rizzolatti and Craighero, 2004) that the neural mechanisms of motor imitation received attention. These neurons are found in the ventral premotor cortex (area F5) and in the inferior parietal lobule (area PF). Both of these brain areas are interconnected and also connect with the superior temporal sulcus, which contains visual neurons that respond to seeing the actions of others. The mirror neurons are active

when monkeys perform goal-directed actions themselves and when they observe someone else performing that action. This circuitry, which enables the coding and mapping of observed actions onto the motor repertoire of the observer, would seem important for imitation. Indeed, in humans, areas 44 and 45 of the left inferior frontal gyrus, a region subsumed by Broca's area and the homolog of monkey F5, is specialized for imitation according to functional magnetic resonance imaging studies. As further detailed by Iacoboni (2005) this 'core circuitry' communicates with other neural systems depending upon the type of imitation performed (imitative learning or social mirroring); mirror neurons in monkeys and humans code the likely future actions of others enabling the anticipation of others' intentions; and mirror neurons in monkeys can change their activation responses according to observational experience, potentially enabling the learning of novel actions as required in imitation.

There is little doubt that the laboratory experimental approach has greatly enhanced the understanding of the processes that can result in social learning and their underlying mechanisms, and developed the methodologies and conceptual tools to further that understanding.

Studies of Animal Culture

The question of whether nonhuman animals exhibit culture, and the importance of this for understanding human behavior, depends fundamentally on definitions of culture. Definitions range from those that deem a species cultural if it merely exhibits traditions transmitted via social learning to those requiring that transmission involve teaching, imitation, or the generation of group-specific norms and ethnic markers. One point of consensus is the necessity, if not sufficiency, of social learning in underpinning culture. Thus, studies of social learning in nonlaboratory animals, in their natural habitat, become paramount. One of the earliest such studies was carried out in a population of Japanese macaque monkeys, where a young female began washing sweet potatoes provisioned on a beach before eating them. This previously unobserved behavior was subsequently seen to increase in frequency in the troop, with 90% of individuals eventually adopting the potato-washing behavior, presumably by learning from each other. There are hundreds, perhaps thousands, of such reports of the spread of novel behavior patterns in populations of animals. Well-known examples include the transmission of dietary preferences by rats attending to cues on each other's breath, the transmission of predator recognition in birds, mammals, and fish, the learning of vocal dialects in song birds, feeding on pine cones among black rats, and tool-using traditions in primates (see Bonner (1980) and Laland and Galef (2009) for readable overviews).

Probably, all vertebrates and many invertebrates will eventually be found to exhibit some form of social learning. Of note, these reports are observations of acquired behavior patterns spreading through single populations. In other cases, distinct cultural variations may characterize the behavioral repertoires of different populations of the same species. For instance, much birdsong is thought to be learned from older males, and frequently regional song dialects characterize neighboring populations. Undoubtedly, the most impressive case of local cultural traditions is provided by the different tool-using repertoires of populations of common chimpanzees. For instance, ant-dipping (using a stalk to fish for ants) is reported in some but not all chimpanzee populations and is thought to be maintained within populations through social learning processes. A now famous study documented 39 different behavior patterns, including tool usage, grooming, and courtship behaviors, that were habitual in some chimpanzee communities and absent in others, where ecological and genetic explanations had been discounted or deemed implausible (Whiten et al., 1999). Subsequently, there have been a number of high-profile, and oft-debated, reports of 'culture' in wild animals using this method, including in bonobos, macaques, capuchin monkeys, cetaceans, and orangutans.

These field reports are of great value in documenting the breadth of animal cultures and throwing light on the contexts in which social learning occurs. Indeed, without an understanding of social learning in the context in which it evolved, we cannot hope to elucidate the interaction between biological and cultural evolution. However, it is difficult in the field to establish reliably whether or not a behavior genuinely is socially learned (as opposed to learned independently by each animal), to determine whether local traditions reflect different cultural repertoires or varying ecological resources, or to investigate the psychological and social processes underlying the diffusion (Laland et al., 2009). The result has been a heated debate, which some have gone so far as to describe as 'war' (McGrew, 2002), about the reality of purported cultural behaviors in animals. Take, for example, the aforementioned case of chimpanzee ant-dipping. At Gombe in Tanzania, a long wand is inserted into nests, withdrawn as the ants swarm up it, and then run through the hand forming the ants into a ball that is then placed in the mouth. In contrast, in the Tai forest of the Ivory Coast a short stick is used that is then pulled directly through the mouth. The question arises as to why the Tai chimps use this seemingly less efficient technique when sticks of varying lengths are available at both sites. Is the difference purely cultural? Researchers studying at a third site, Bossou, discovered that the technique used was correlated with the species of ant being captured (Humle and Matsuzawa, 2002). They discovered, through using themselves as guinea pigs, that black ants swarm up sticks more aggressively and give more painful bites than red ants. Not surprisingly then, chimpanzees at Bossou use long sticks for black ants and short ones for red ants. These findings suggest caution is required when inferring a cultural explanation, but they do not indicate whether dipping techniques reflect differing ant prey at Tai and Gombe. Indeed, a recent study, comparing ant-dipping at 13 African sites, suggested that variation in techniques cannot be explained by the ants present (Schoening et al., 2008). For some, whether or not ant-dipping varies according to prey ferocity is beside the point: Byrne (2006) believes that the hallmark of culture is intricate complexity of behavior, and as the skill of ant-dipping is intricate and unlikely to be learned in its entirety by a solitary chimpanzee, there is an implied role for social learning.

Thus, hard evidence that putative animal traditions are socially learned is required. Researchers have invested their energies in two complementary approaches to remedy this situation: captive transmission chain and diffusion studies, and

statistical methods that may be applied to studies of wild animals. Attempts to investigate animal cultural traditions experimentally have moved away from the demonstrator–observer dyadic approach toward group-level studies under controlled conditions in captivity. 'Diffusion studies' are characterized by the introduction of a trained demonstrator to a population and a careful monitoring of the increase in the number of individuals displaying the target behavior over time (Lefebvre and Palameta, 1988). 'Transmission chain studies' involve the gradual replacement of a founder population of trained demonstrators with untrained animals (replacements representing the turnover of pseudogenerations) and explore whether the target behavior persists in the population when the trained founders have been removed (Laland et al., 1993). For example, studies of captive chimpanzees, involving the use of novel extractive foraging tasks (or 'artificial fruits'), have shown they can sustain foraging traditions, across pseudogenerations, through high-fidelity social learning (ensuring the behavior remains unaltered over time) and even transmit traditions from one group to another (Whiten et al., 2007).

Many such studies have been performed with a variety of species (reviewed by Whiten and Mesoudi, 2008) and have been valuable in determining how processes of social interaction impede, or propitiate, the diffusion of information. It became apparent that the structure of animal populations (dominance relations, familiarity of individuals, spatial positioning, sex, age, and size differences) strongly influences the pathways by which learned information spreads, a phenomenon known as 'directed social learning' (Coussi-Korbel and Fragaszy, 1995). For instance, novel skills often spread at different rates among juveniles and adults, among the two sexes, or within and between family groups (see Section The Adaptive Value of Animal Social Learning). However, although these findings add credence to the supposition that social learning is behind intersite variation in behavior, and the factors that may influence transmission, they do not tell us whether social learning can be implicated in natural behavioral variation. This led to researchers identifying social learning more directly in the wild using innovative experiments (reviewed in Reader and Biro, 2010), quantitative analyses (Sargeant and Mann, 2009; Whitehead, 2009), and proxy measures of social learning, such as patterns of affiliation and observation. For instance, both in capuchin monkeys and chimpanzees, there is evidence that individuals selectively watch others from whom they can learn skills they have yet to master (Biro et al., 2003; Perry et al., 2003).

More recently, researchers have begun to develop statistical methods for assessing the likelihood of asocial learning being responsible for an observed pattern of behavior, permitting inference of social learning when asocial learning has been deemed improbable (Kendal et al., 2009b; Franz and Nunn, 2009; reviewed in Kendal et al., 2010). Others have fit mathematical models to phylogenetic data to tease apart the role of genetics and culture in population-level behavioral variation (Lycett, 2010). These methods have been applied to captive populations as well as to wild lemurs, capuchin monkeys, chimpanzees, cetaceans, song birds, meerkats, and other species. Although the field has come far in recent years in being able to identify social learning in the wild, we still do not know what social learning processes are actually involved (but see Kendal et al., 2007; Hoppitt et al., 2012) and the role of factors such as directed social learning. However, as many of these new methods take advantage of social network theory, they will facilitate investigation of directed social learning and/or transmission biases (see Section The Adaptive Value of Animal Social Learning) in the spread of information within and between populations.

Typically, the new behavior pattern found in an animal culture will have been invented by a single individual. There has been comparatively little investigation of the process of innovation. It is not clear whether innovation should be characterized as a personality trait (associated with clever, creative, neophilic, or nonconformist individuals), a state-dependent variable (e.g., hunger may drive foraging innovation), or resulting from environmental changes (such as a drought) (Reader and Laland, 2003). Studies in fish (Laland and Reader, 1999), meerkats (Thornton and Samson, 2012), and primates (Reader and Laland, 2001) suggest that the adage 'necessity is the mother of invention' may be appropriate, with innovation appearing at elevated frequencies in hungry, low status, and small individuals. In contrast, a study of Callitrichid monkeys found that while younger individuals were more inquisitive, it was the older individuals who had the competence to innovate (Kendal et al., 2005a). Across primate species, incidence of innovation covaries with incidence of social learning (also with tool use and deception), suggesting that innovation and social learning may be manifestations of a general capacity for behavioral plasticity (Reader and Laland, 2002). Likewise, studies of birds indicate that innovation, or behavioral plasticity, is correlated with invasion success of species and thus their ability to overcome anthropogenic change to environments (Sol et al., 2002). However, within a given species it is not known whether innovative individuals tend to be good, average, or poor social learners. One recent study has, however, shown that in pigeons, at least, social and asocial learning abilities are positively correlated such that the two abilities are not traded off within individuals (Bouchard et al., 2007).

The Adaptive Value of Animal Social Learning

Theoretical analyses have explored the circumstances under which natural selection will favor reliance on social learning, as opposed to asocial learning or evolved nonlearned behavior (see Laland et al. (1996), for an overview of this literature). A consensus has been reached that the issue hangs, in part, on patterns of variability in the environment. In an environment that is changing comparatively slowly, or that exhibits relatively little spatial heterogeneity in resources, populations are able to evolve appropriate behavior patterns through natural selection, and learning is of little adaptive value. In contrast, in rapidly changing or highly variable environments, asocial learning pays. Here, natural selection cannot track environmental fluctuations quickly enough, while social learning is unreliable because it may lead individuals to acquire outdated or locally inappropriate behaviors. It is intermediate rates of change and patterns of spatial heterogeneity that favor social learning, and within this window vertical transmission of information (social learning by offspring from parents) is thought to be an adaptation to slower rates of change than horizontal

transmission (social learning among unrelated individuals of the same cohort).

Although these findings are theoretically robust, it is only recently that they have begun to be validated with empirical studies of animals (reviewed in Kendal et al., 2005b, 2009). For instance, we did not know whether contemporary populations of animals capable of social learning actually do switch between social and asocial learning depending on the pattern of environmental variability they experience in pertinent resources. Providing a partial answer to this question is a study of wild-caught sticklebacks where the fish ignored social information provided by other foraging conspecifics when their personal foraging information was highly reliable (representing a nonvariable environment), but were more likely to copy others as their own information became outdated and thus potentially unreliable (van Bergen et al., 2004).

More generally, attention has recently turned to what other factors affect reliance on social learning. For instance, is social learning more likely when individuals are confronted with an unfamiliar problem, or a threatening environment, or do individuals preferentially acquire social information from others with certain characteristics such as older, higher ranked, or successful individuals? A plethora of studies have been carried out with a variety of species investigating these 'cultural transmission biases' (Boyd and Richerson, 1985), which have also been termed 'social learning strategies' indicating when, what, and whom individuals should copy (Laland, 2004). For example, in the most recent collation of such studies (Rendell et al., 2011), there is evidence of 'context-dependent biases' regarding (1) the state of the observer (e.g., copy when uncertain or in a reproductive state), (2) the characteristics of the model (e.g., copy old, large, high status, or familiar individuals), and (3) the frequency of the to-be-copied behavioral trait in the population (e.g., copy if rare or in the majority). As many of these studies are conducted in highly controlled laboratory-type studies, we do not know, however, the extent to which these transmission biases function independently or in concert in freely living animals and how they influence the cultural patterns observed in wild animals. Preliminary evidence with chimpanzees indicates that multiple biases (including copy when uncertain and of low status, copy high-ranked and expert individuals) may be in play in the transmission of a single simple foraging tactic. Moreover, it is possible that transmission biases such as copy highly ranked individuals or 'conformity' (an exaggerated tendency to copy the majority) may explain intersite variation in chimpanzee cultural repertoires despite the sharing of ecology and migrants (Kendal et al., in preparation).

Social Learning and Social Intelligence

Social learning has been central to a number of social intelligence hypotheses, which suggest that complex social behavior drove brain evolution and intelligence. Allan Wilson's (1985) concept of 'behavioral drive' explicitly emphasizes social learning. Wilson noted a positive relationship between relative brain size and rate of evolution in vertebrates. He explained this by arguing that big-brained species exhibit greater behavioral plasticity, are more innovative, and are more capable of social learning than small-brained species. Cultural traditions, he argued, allow populations of animals to open up new niches and exploit novel resources, thereby exposing themselves to new selection pressures (known as 'niche construction,' Odling-Smee et al., 2003; Sterelny, 2007) and accelerating the rate of fixation of mutations. Wilson's hypothesis is supported by recent evidence that there is a significant correlation between relative brain size and incidence of both innovation and social learning in primates (Reader and Laland, 2002) and birds (Nicolakakis et al., 2003) and the intraspecific correlation of social and asocial learning in pigeons (Bouchard et al., 2007). Likewise, the enhanced cognition of 'enculturated' apes (e.g., Kanzi's language performance), raised by humans who emphasized socially guided exploration opportunities (Tomasello and Call, 2004), may be taken as consistent with this hypothesis.

More recently, researchers have put forth the 'Cultural Intelligence Hypothesis' as opposed to the 'General Intelligence Hypothesis.' For Herrmann et al. (2007), who gave a battery of tests to orangutans, chimpanzees, and 2.5-year-old children, this is evidenced in the fact that all species performed similarly in the domain of physical cognition but the children outstripped the other species when it came to social cognition. Thus, they propose that humans have a set of social cognitive skills (theory of mind, social learning, communication), emerging early in ontogeny, for participating and exchanging knowledge in cultural groups. In a study of what underlies the apparently human unique capability of cumulative culture (the increase in complexity or efficiency of cultural artifacts across generations), Dean et al. (2012), when comparing capuchin monkeys, chimpanzees, and children, also isolated sociocognitive factors including imitation, complex communication, and prosociality. Similarly, Whiten and van Schaik (2007) note a cross-species correlation of possession of complex culture (defined as a repertoire of multiple traditions) and social intelligence supporting culture (e.g., imitation), namely in the great apes. They admit, however, the paradox of robust findings of imitation in birds yet little evidence for possession of cultural repertoires, and vice versa for monkeys.

(For further details regarding the input of comparative studies of cultural cognition and material culture artifacts on understanding the evolutionary origins of humanity's socio-cognitive niche, see Whiten and Erdal, 2012 and Haslam et al., 2009, respectively.)

Implications for Conservation and Animal Welfare

Despite any controversies within the study of animal social learning and culture, the field has important implications for ethics, philosophy, and politics. Continuity of the human and the nonhuman animal mind affects ethical considerations in animal welfare and influences how we characterize humans' place in nature. Similarly, an understanding of animal cultures can be used to enhance the conservation and management of species facing extinction, as well as influencing conservation priorities through increasing awareness of the existence of not only genetic, but also cultural diversity in animals (for a review see Whitehead, 2010).

Social Learning Theory and Crime

Jeffrey T Ward and Chelsea N Brown, University of Texas at San Antonio, San Antonio, TX, USA

Abstract

Social learning theory (SLT) is a leading explanation of criminal behavior which maintains that crime is learned and more likely to occur when individuals differentially associate with people who are criminally involved, experience greater exposure to delinquent models, anticipate or actually receive more rewards and fewer punishments for crime, and have a greater number of definitions favorable to crime. Empirical tests have garnered moderate to strong support for the theory. SLT serves as the foundation for many delinquency prevention and offender treatment programs, and has recently been merged with social structural concepts into a social structure–social learning model.

Social learning theory (SLT) (Akers, 1973) is a logically consistent and empirically testable theory formulated to explain the full spectrum of criminal and delinquent behaviors. The theory is capable of accounting for both generalization and specialization in offending. SLT maintains that criminal behavior is learned in the same manner that any human behavior is acquired. The fundamental ideas of SLT stem from Sutherland's theory of differential association and the principles of operant conditioning, which were first integrated in a multidisciplinary effort by Robert Burgess and Ronald Akers in 1966. In the decade to follow, Akers continued his work with the theory and advanced the 'social learning' terminology. In its current form, SLT maintains there are four central concepts that include differential association, imitation, definitions, and differential reinforcement. The main idea of SLT is that crime is more likely when individuals interact with and are exposed to people who are criminally involved and support delinquent conduct (differential association), experience greater exposure to delinquent models (imitation), anticipate or actually receive more rewards and fewer punishments for delinquent behavior (differential reinforcement), and have a greater number of definitions favorable to committing delinquency (definitions). Studies testing the key propositions of the theory have yielded strong empirical support, especially for the differential association and definitions variables (see Pratt et al., 2010). In addition to being one of the leading accounts of criminal behavior, SLT has important practical implications for crime control strategies and serves as the foundation for several successful offender treatment programs.

The Roots of SLT

SLT is the product of theoretical ideas, which cut across the disciplinary boundaries of sociology and psychology. The general notion that learning plays a pivotal role in the development of criminal and delinquent behavior can most directly be traced back to the works of sociologist Edward Sutherland, whereas the details of the learning process can be found in the writings of behavioral psychologists, most notably of which include B.F. Skinner. In a deductive theoretical integration effort in 1966, Robert Burgess and Ronald Akers took on the task of folding the central ideas of differential association theory into the broader principles of operant conditioning; their efforts resulted in the formation of a new theory known as differential association-reinforcement theory (see Burgess and Akers, 1966).

The foundations of differential association-reinforcement theory (and ultimately SLT) begin with Sutherland's theory of differential association which contains nine propositions as follows:

1. Criminal behavior is learned.
2. Criminal behavior is learned in interaction with other persons in a process of communication.
3. The principal part of the learning of criminal behavior occurs within intimate personal groups.
4. When criminal behavior is learned, the learning includes
   a. techniques of committing the crime, which are sometimes very complicated and sometimes very simple, and
   b. the specific direction of motives, drives, rationalizations, and attitudes.
5. The specific direction of motives and drives is learned from definitions of the legal codes as favorable or unfavorable.
6. A person becomes delinquent because of an excess of definitions favorable to violation of law over definitions unfavorable to violation of law.
7. Differential associations may vary in frequency, duration, priority, and intensity.
8. The process of learning criminal behavior by association with criminal and anticriminal patterns involves all the mechanisms that are involved in any other learning.
9. Although criminal behavior is an expression of general needs and values, it is not explained by those general needs and values, because noncriminal behavior is an expression of the same needs and values (Sutherland, 1947: pp. 6–7).

In sum, these nine propositions make clear that learning is fundamental to the origins of criminal behavior and draws attention to the importance of attitudes (definitions) in determining which individuals will be law violators. However, differential association theory falls short of providing a comprehensive explanation of how individuals learn criminal behavior.

In 1965, Ronald Akers was hired as an assistant professor at the University of Washington and worked alongside Robert Burgess, who was also an assistant professor and extensively

trained in the principles of behavior modification. Akers' vast expertise in criminological theory and Burgess' knowledge of fundamental behavioral learning principles resulted in a collaborative effort to restate and reformulate differential association theory in terms of the principles of operant conditioning. In explicating their theory, Burgess and Akers omitted (proposition 9), merged (propositions 1 and 8), and further specified (propositions 2 through 7) the original propositions contained in Sutherland's theory. Specifically, the reformulated propositions found in differential association-reinforcement theory are as follows:

1. Criminal behavior is learned according to the principles of operant conditioning.
2. Criminal behavior is learned both in nonsocial situations that are reinforcing or discriminative and through that social interaction in which the behavior of other persons is reinforcing or discriminative for criminal behavior.
3. The principal part of the learning of criminal behavior occurs in those groups which comprise the individual's major source of reinforcements.
4. The learning of criminal behavior, including specific techniques, attitudes, and avoidance procedures, is a function of the effective and available reinforcers and the existing reinforcement contingencies.
5. The specific class of behaviors which are learned and their frequency of occurrence are a function of the reinforcers which are effective and available and the rules or norms by which these reinforcers are applied.
6. Criminal behavior is a function of norms which are discriminative for criminal behavior, the learning of which takes place when such behavior is more highly reinforced than noncriminal behavior.
7. The strength of criminal behavior is a direct function of the amount, frequency, and probability of reinforcement (Burgess and Akers, 1966: p. 146).

In addition to maintaining an emphasis on social interaction and definitions as critical to the learning process, differential association-reinforcement theory clearly draws attention to the importance of reinforcement for learning criminal behavior. In fact, their sixth proposition claims that the degree to which individuals learn definitions favorable to law violations stems from levels of reinforcement. By using the principles of operant conditioning to reformulate the theory of differential association, Burgess and Akers were able to generate propositions that were more specific and testable. In the years that followed, Burgess turned his attention to other scholarly pursuits while Akers began a long career working with the theory that included further specification and the adoption of the 'social learning' nomenclature (e.g., see Akers, 1973), comprehensive empirical testing (e.g., see Akers et al., 1979), and the development of a cross-level theoretical integration of SLT with social structural explanations of delinquency (e.g., see Akers, 2009).

Akers' SLT

Akers' SLT holds that criminal behavior is learned, maintained, and modified in the same manner as any human behavior. According to the theory, what differentiates delinquent behavior from conforming behavior is the learning content not the learning process itself. While SLT is intended to be very general and encompasses all facets of the learning process, four central concepts form the cornerstone of the theory that include *differential association*, *imitation*, *definitions*, and *differential reinforcement*. Generally speaking, SLT suggests that individuals will be more likely to engage in criminal behavior when they have greater associations with people who engage in criminal behavior, greater exposure to delinquent models, more definitions favorable to criminal involvement, and greater actual or perceived rewards and benefits associated with criminal behavior.

Differential Association

Differential association provides the context in which learning occurs. According to the theory, the most important contexts for learning criminal behavior include peer groups and family units, though varying entities such as schools, neighbors, and media also provide alternative settings where some learning of criminal behavior may ensue. There are two fundamental aspects of differential association, namely the behavioral-interactional and normative dimensions. The behavioral-interactional dimension refers to the direct and indirect interactions and associations with individuals that engage in delinquent activities. The normative dimension refers to the values which one is exposed to as a result of one's associations and interactions with others. It is worth noting that the normative dimension was inherent in Sutherland's original theory; Akers' formulation of SLT keeps the normative dimension but adds the behavioral-interactional dimension to the overarching differential association construct. As differential associations set the learning context, SLT anticipates that the learning mechanisms including imitation, definitions, and differential reinforcement are in large part influenced by one's differential associations. For instance, the theory suggests that individuals with a greater proportion of their peers who engage in criminal behavior will be exposed to more delinquent models, will be subjected to a greater number of definitions favorable to delinquency, and will perceive more rewards and benefits associated with criminal conduct. In turn, these individuals will be more likely to engage in criminal behavior. In other words, the effect of differential association on criminal behavior is hypothesized to, at least in large part, be mediated by the imitation, definitions, and differential reinforcement variables.

Imitation

Imitation, or reproducing the actions of others, is a fundamental learning mechanism influencing behavior of all types across various developmental periods including childhood, adolescence, and adulthood. Imitation in the context of crime occurs when an individual commits a criminal act following the observation of someone else engaging in a similar crime. Observation most typically involves viewing someone's behavior directly in person, but viewing an individual's behavior indirectly through media or receiving verbal or written instructions specifying how to engage in criminal

behavior are alternative forms of observation. Imitation is thought to be most relevant when learning new criminal activities, though it can continue to exert some influence even on previously witnessed behaviors. Importantly though, individuals tend to not mindlessly reproduce the behavior that they observe; rather, characteristics of both the criminal model and the behavior itself weigh into the decision of whether the behavior will be imitated. In addition, beliefs about whether a behavior will be met with rewards as opposed to punishments are also highly relevant in determining if a behavior is likely to be imitated. This means that the learning mechanisms in SLT do not act to influence criminal behavior in isolation. Thus, individuals can technically learn how to commit criminal behavior through observation but elect not to actually commit any criminal acts due to lack of reinforcement and/or acquired definitions unfavorable for crime. It is worth noting that principles of 'observational' learning have been extensively developed elsewhere (see Bandura, 1977). According to Bandura, imitation requires individuals to pay attention to the model, to retain knowledge of what they witnessed, to be physically able to reproduce the behavior, and to be motivated to imitate the behavior. While Akers' theory encompasses these nuances, the proposition at a basic level states that individuals who are exposed to more criminal models will be more likely to engage in crime; and, exposure to criminal behavior that can be imitated is largely a function of one's differential associations.

Definitions

Definitions refer to one's attitudes or beliefs concerning the moral appropriateness or justifiability of criminal behavior. Definitions operate at both a specific and a general level. In other words, people may have general definitions unfavorable to crime but nevertheless engage in a particular type of criminal behavior because they have specific definitions favorable to this form of behavior. For example, a white-collar criminal may believe ordinary street crime to be morally reprehensible but feels that insider trading is justifiable in the realm of business. Another important consideration in SLT is that definitions favorable toward crime can either fully embrace the moral appropriateness of crime (positive definitions) or rationalize or excuse the deviant behavior (neutralizing definitions). In some subcultures, for example, violent behavior is embraced and a 'code of the street' guides comportment in everyday life (see Anderson, 1999). Even more radical are the definitions favorable to violence held by terrorists. While extreme values held by subcultures and extremist groups can generate high levels of criminal behavior, delinquency commonly occurs among those not possessing such positive definitions favorable to crime. Loosely held conventional values themselves open up the possibility for criminal learning, and neutralizations serve to rationalize or justify criminal behavior under certain circumstances.

Individuals form definitions favorable or unfavorable to delinquency through exposure to other's attitudes through their differential associations with delinquents and through the other learning mechanisms including imitation and differential reinforcement. Thus, attitudes toward specific or general acts of crime may be strengthened when one witnesses the behavior of others and believes or finds the criminal behavior to be rewarding. Once acquired, definitions work to influence behavior by making crime an approved or acceptable behavioral option, thereby making an individual more willing to take advantage of a criminal opportunity in a specific type of situation or, perhaps, in situations more generally.

Differential Reinforcement

Differential reinforcement concerns behavioral conduct in response to actual and perceived rewards and punishments associated with engaging in behavior. In general, SLT suggests that individuals who experience and perceive more benefits and fewer costs will have a greater likelihood of engaging in criminal behavior. In other words, criminal behavior is more likely when reinforcement toward criminal behavior is stronger and punishment is weaker. According to the logic of operant conditioning from which SLT heavily draws, reinforcement and punishment can each take two forms – positive and negative – thereby creating four fundamental learning scenarios that modify human behavior. Positive reinforcement involves receiving actual rewards or anticipating receiving rewards (e.g., obtaining goods) for engaging in crime. Negative reinforcement involves escaping punishment or detection. Either way, both positive and negative reinforcement are expected to result in a strengthening of criminal behavior. Conversely, both positive and negative punishment are expected to result in a weakening of behavior according to fundamental learning principles. Positive punishment involves the experience of formal or informal consequences as a result of engaging in the behavior, whereas negative punishment involves the failure to obtain rewards or positive results.

The rewards and punishments associated with crime can be social or nonsocial in nature. Social reinforcers and punishers of criminal behavior can take many forms such as peer approval or acquired goods. Importantly, however, something that might be a social reinforcer for one individual may be a social punisher for another depending on one's differential associations. Hence, peer disapproval would be the likely response to criminal involvement among individuals who associate with prosocial peers; whereas, peer approval would be the expected response to deviancy if one's peers are delinquent. Nonsocial reinforcers (and punishers) can also have important influences on behavior such as the physiological effects of drugs. According to SLT, nonsocial reinforcers tend to interact with the other learning mechanisms. For example, individuals' experiences from the physiological effects of drugs are argued to be colored by the definitions they are exposed to and the reinforcement they receive from their differential associations. Further, reinforcers and punishers that influence behavior need not be tangible or even directly received. Some religious extremists believe jihadist actions (i.e., criminal behavior) will result in rewards following death, whereas more conventional religious believers might expect these same behaviors to result in eternal damnation. In sum, criminal behavior is a direct product of the amount, frequency, and probability of reinforcement, which has been shown to be a complex construct that can take a variety of forms. Overall, the crux of the differential reinforcement concept in SLT suggests that individuals will be more likely to engage in

criminal behavior as positive (and negative) reinforcement is increased and positive (and negative) punishment is decreased.

Empirical Tests of SLT

The collective body of empirical research testing the core hypotheses of SLT provides moderate to strong support for the theory (Pratt and Cullen, 2000; Pratt et al., 2010). Studies assessing social learning examine the effects of one or more of the learning variables (i.e., differential association, imitation, definitions, and differential reinforcement) on criminal outcomes. In a classic first empirical test of SLT, Akers et al. (1979) used data that they collected from 3065 Midwestern middle and high school students to examine the individual and combined effects of all four social learning variables on alcohol and marijuana use. The social learning variables explained a very high proportion of the variance in these antisocial behaviors. Full models including all the four social learning variables explained 54% of the variance in alcohol use and 68% of the variance in marijuana use. Further, additional analyses revealed the relative importance of each of the social learning constructs; the rank ordering from most to least influential included differential association, definitions, differential reinforcement (social/nonsocial), differential reinforcement (social), and imitation. Other studies using these same data from the Boys Town study on alcohol and drug use demonstrate that the relative influence of social learning variables is greater than variables from other theoretical perspectives including social control and strain (Krohn et al., 1984; Akers and Cochran, 1985; Akers and Lee, 1999).

In addition to the Boys Town study, Akers was involved in other major projects including a panel study on adolescent smoking behavior (see Lauer et al., 1982) and another longitudinal study on the drinking behavior of elders (see Akers et al., 1989). In short, several empirical studies stemming from these alternative data sets also find support for the independent and collective effects of social learning variables on delinquency. Outside of Akers' own work, SLT is not typically tested in a comprehensive fashion and the details of the learning 'process' are infrequently the subject of explicit empirical investigation in criminological studies. Put differently, most studies examining SLT tend not to include measures of all the learning variables within the same study. In fact, many studies include only measures of differential association (e.g., peer delinquency) which is highly problematic because it becomes impossible to determine the mechanisms by which others' delinquency impacts a respondent's delinquency. By including only the concept of differential association in empirical tests of social learning, all of the effort by Akers to clarify Sutherland's vague and incomplete statements concerning the process of criminal learning is snubbed. Understanding how differential associations come to influence behavior is of critical theoretical importance (Warr, 2002). There are many potential mechanisms by which groups can influence behavior including, for example, loyalty, fear of ridicule, status, collective processes, and social learning (see Warr, 2002). Not surprisingly, Akers argues these mediating variables can be subsumed into the four existing variables of SLT.

Pratt et al. (2010) recently elucidated the empirical status of SLT through a meta-analysis of roughly 700 effect sizes from 133 studies that assessed the effects of one or more of the social learning variables. Differential association, definitions, differential reinforcement, and imitation represented approximately 55, 20, 20, and 5% of the effects examined in the meta-analysis respectively; hence, differential association is tested quite frequently in social learning models, whereas imitation is hardly ever included as a predictor of delinquent outcomes in criminological research. It is worth noting that SLT is mostly tested examining the influences of delinquent peer associations on delinquent and criminal behavior. The differential association effects of peers tend to be stronger than the differential association effects of other individuals including parents. For the learning variables overall, the mean effect size estimates demonstrate the strongest and most consistent support for differential association (0.225) and definitions (0.218). For these two variables specifically, tests for the effect estimates were statistically significant at least 70% of the time. Comparatively, differential reinforcement effects were statistically significant 56% of the time, whereas imitation effects were significant only 47% of the time. Moreover, the mean effect estimates for differential reinforcement (0.097) and imitation (0.103) were much lower. Taken together, the differential reinforcement and imitation variables have both weaker and less consistent influences on criminal outcomes than the differential association and definitions variables.

Overall, the key hypotheses of SLT receive empirical support, especially those concerning the effects of differential association and definitions on crime and delinquency. Before accepting this conclusion, however, a highly controversial measurement issue having important implications for the empirical validity of differential association warrants mention. There are two primary strategies to assess whether one is in differential association with delinquents. First, indirect measures of peer delinquency involve asking respondents about the behaviors of their peers (as well as about their own behaviors). Second, direct measures of peer delinquency involve asking respondents and their peers to each self-report their own behaviors. Thus, in the direct measurement approach, information about the peer's behavior comes directly from the peer himself or herself. The central concern with perceptual peer delinquency (indirect) measures is that respondents may 'project' their own delinquent tendencies into their perceptions of their peers, thereby artificially inflating the correlation between peer and respondent behaviors (Gottfredson and Hirschi, 1990). Indeed, indirect measures of peer delinquency reveal stronger effects on delinquency than do direct measures (Boman and Gibson, 2011; Meldrum et al., 2009; Weerman and Smeenk, 2005). To skirt this potential for projection bias, several peer delinquency researchers recommend using the direct measures of peer delinquency (peer self-reports), potentially captured via social network data. Akers vehemently maintains that it is the perception of the peer's behavior, not the actual behavior of the peer, which matters most in learning. This epistemological debate concerning the correct measurement strategy is unlikely to be reconciled through empirical means since attempts to construct peer delinquency measures that are perceived accurately enough to avoid potential bias have been unsuccessful (see Boman et al.,

2012a,b). Nevertheless, what is important for SLT's legacy is while the effects of differential association are attenuated when employing direct measures of peer delinquency they are often still of statistical and practical significance.

Practical Applications of SLT

As an explanation of crime, SLT suggests that criminal behavior is learned and is the product of one's differential associations, imitations, definitions, and differential reinforcement. Fortunately, learned behavior can be unlearned too. That is, SLT maintains it is possible for criminals to learn conforming behavior if their differential associations, definitions, reinforcement contingencies, and models are altered to promote prosocial influence. As a more proactive approach, at-risk youth can be targeted for delinquency prevention as well. Systematic reviews suggest that applied criminology that incorporates the fundamental ideas of learning, including cognitive behavioral therapy, is among the most effective approaches to delinquency prevention and offender treatment (Lipsey et al., 2007).

Applications of learning principles to delinquency prevention efforts and offender treatment programs are commonplace. Sometimes learning principles only loosely guide justice policy as is the case with the Gang Resistance Education and Training (G.R.E.A.T.) initiatives (see Akers and Sellers, 2009). The G.R.E.A.T. program consists of law enforcement-guided classroom instruction in schools, taking a preventative approach to the problems of youth delinquency, and gang involvement. Classroom instruction is intended to generate attitudes unfavorable to gang membership and to enhance police–citizen relationships which, in turn, should help to reduce community problems associated with gangs. Perhaps due to weak adherence to the learning principles, the empirical results of G.R.E.A.T. were not so great (see Esbensen et al., 2001). While some program efficacy measures were indicative of success including the development of more negative definitions of gang membership and greater association with prosocial peers, there were no statistically significant effects of the program on the fundamental outcomes of interest. Specifically, participants in the program were not less likely to join a gang and did not engage in lower levels of delinquency than nonparticipants. As a result of these findings, the program has undergone a comprehensive makeover (G.R.E.A.T. II) but preliminary findings of this modified program are only slightly more promising; short-term gang involvement, but not general delinquency, appears to be reduced by the program (Esbensen et al., 2011).

Other programs are more cleanly influenced by social learning concepts such as the Adolescent Transition Program (ATP) from the Oregon Social Learning Center. Focusing on parents and family dynamics, ATP involves 12 therapist-led interactive parent group sessions and 4 individual family meetings designed to enhance parental management skills including monitoring, socialization, and appropriate discipline. The logic of the program is that parents themselves need to learn appropriate techniques to effectively socialize their children. Evaluations of the program have shown that parents do learn positive parenting skills and, as a result, their children's delinquency decreases (Dishion et al., 1992). It is worth mentioning that other programs out of the Oregon Social Learning Center, including the Multidimensional Treatment Foster Care and Interests of Families and Teachers initiatives, also serve as exemplary models of the application of social learning principles to crime prevention and offender treatment effects.

The Social Structure–Social Learning Model

In 1998, Akers published the first edition of his book *Social Learning and Social Structure: A General Theory of Crime and Deviance*, which summarizes SLT and his research endeavors and, importantly, presents a model that incorporates macro- and mesolevel structural factors with SLT. The integrative approach taken this time was not a deductive one but rather sequential or 'end-to-end' one. According to the social structure and social learning model (SSSL) (Akers, 2009), the four social learning variables maintain their proximate effects on behavior as in the original theory. New to the model, however, are four social structural dimensions (i.e., differential social organization; differential location in the social structure; theoretically defined structural variables; and differential social location in primary, secondary, and reference groups). These constructs are hypothesized to influence individuals' behavior through their effects on the social learning variables. Importantly, the model argues that community crime rates are not directly related to social structural forces. Rather, Akers (2009) maintains that differential association, imitation, definitions, and differential reinforcement mediate the effects of social structure on crime rate. In short, social structure sets the context in which individuals learn criminal (or conforming) behavior and crime rates simply reflect how much criminal learning has occurred at the community or societal level.

Differential social organization refers broadly to the social structural correlates of crime including factors such as population density, urbanicity, and region. These features organize communities and societies toward or against crime. *Differential location in the social structure* refers to sociocultural and sociodemographic differences in communities and societies across class, gender, race, age, and religion. At the collective level these variables such as youth concentration or proportion Black serve to identify the locations or statuses of groups in the larger social structure. The *theoretically defined structural variables* concept is a catch-all dimension that encompasses fundamental structural perspectives about the sources of crime, the most important of which include anomie, conflict, and social disorganization. Finally, *differential social location in primary*, *secondary*, and *reference groups* refers to peoples' positions in peer, work, and family groups. These groups serve as the immediate context through which the other social structural dimensions impact individuals and have the most direct link to the social learning variables. Specifically, this construct in particular is closely intertwined with the differential association concept.

In sum, the four dimensions of social structure organize groups, neighborhoods, and societies, thereby setting the context for learning either law abiding or criminal behavior. Importantly, these social structural factors are hypothesized to influence individual behavior through the learning

mechanisms outlined in SLT, meaning that group crime rates signify higher levels of aggregate criminal learning in communities. Overall, post hoc interpretations of previous research not intended as explicit tests of the SSSL model lend support for its basic propositions. However, the empirical status of the model will remain unclear until comprehensive tests of the model are conducted (Akers, 2009).

Conclusion

Standard metrics that judge the quality of theories include parsimony, scope, logical consistency, testability, empirical validity, and practical utility. When SLT is viewed in light of these criteria, the theory holds up well. SLT contains only four key components, can explain a wide range of criminal and delinquent behaviors, has clear concepts, makes straightforward hypotheses, receives empirical support, and is one of the more useful theories for criminal justice policy. Of the four social learning variables – differential association, imitation, definitions, and differential reinforcement – it is the concepts of differential association and definitions that receive the strongest empirical support in the literature. This is quite intriguing and suggests that it is the normative aspects of differential association that are most responsible for antisocial conduct, which are the aspects of the theory that pay direct homage to Sutherland's differential association theory. At the same time, SLT is clear in anticipating interdependence between the learning mechanisms. While the theory also suggests there are some feedback effects of the learning mechanisms, it is clear in its suggestion that there is generally a sequence or directional process at play (Akers, 2009). In light of these considerations, it can be argued that the social learning process has been incompletely studied and there is still much to learn about the empirical status of SLT. This is truer still when considering the recent cross-level theoretical integration with macro- and mesostructural social forces, namely SSSL theory (Akers, 2009). At this juncture, it is safe to conclude that learning plays a nontrivial role in the development of criminal and delinquent behavior. Future research should continue to examine the specifics of learning process as well as the social structural conditions that set the contexts for social learning.

Social Mechanism

Petri Ylikoski, University of Helsinki, Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The basic idea behind mechanism-based explanation is simple at its core, it implies that proper explanations should detail the 'cogs and wheels' of the causal process through which the outcome to be explained was brought about. This idea has become increasingly popular in both the social sciences and philosophy of science over the last two decades. At the core of the mechanistic approach is a criticism of widely held views about social scientific explanation, causation, and the nature of social scientific theories. However, it also has interesting methodological implications for the social sciences.

The Rise of Social Mechanisms

The idea of mechanism-based explanation in the social sciences does not have a single origin. The idea has become popular in recent philosophy of science (Craver, 2007), and has begun to have an influence on many social scientists. However, the rise of mechanisms in the social sciences predates the wide adoption of the idea by philosophers of science. In fact, a number of authors seem to have adopted the idea independently of each other and have utilized it to criticize explanatory practices in the social sciences. For these authors, the idea of mechanism-based explanation has provided a useful platform for criticizing existing research practices and views about the nature of the social scientific enterprise. Due to these diverse origins, there are many different definitions of social mechanisms (Mahoney, 2001). This diversity is understandable, as the idea of a mechanism has been used to support quite different methodological and theoretical positions (Hedström and Ylikoski, 2010). In a short review such as this, it is only possible to mention some of the more prominent advocates of mechanistic ideas.

Jon Elster (1989, 2007) is probably the most influential advocate of mechanisms in the social sciences and his many books are full of examples of mechanism-based thinking in action. For him, the core of this thinking is the idea that mechanistic explanations open up black boxes and show the cogs and wheels of the internal machinery underlying the phenomenon. While much of Elster's work has focused more on psychological rather than social mechanisms, his work has had a huge impact on how social scientists think about explanation.

The critical realism movement (e.g., Sayer, 1992; Archer et al., 1998) has been highly influential with respect to thinking in terms of mechanisms. The original source of its ideas about causation and scientific explanation is Rom Hárre's (1970) pioneering work, but the principal inspiration for critical realists has been Roy Bhaskar (1978, 1979). His critical realism is a tight philosophical package of ontological and epistemological views in which the idea of mechanistic explanation is the most intuitive part.

Within philosophy of the social sciences, both Daniel Little and Mario Bunge have been important spokesmen for mechanistic thinking. Little's textbook (Little, 1991) and articles (Little, 1998) show in an accessible way how thinking in terms of causal mechanisms helps to solve various methodological problems which characterize other approaches to the social sciences. Little also strongly emphasizes the important role of microfoundations in mechanistic explanations. Bunge's (1997, 2004) account of mechanistic explanation is part of his more general systemistic philosophy of science. Like Bhaskar, Bunge's ideas about mechanistic explanations are part of a much larger philosophical system. However, his ideas about mechanisms are quite compatible with what others have said about social mechanisms.

In political science, causal mechanisms have played an important role in debates about research methodology and causal inference (e.g., Mahoney, 2001; George and Bennett, 2005; Gerring, 2008). Many authors have presented mechanistic thinking as alternative to statistical methodologies and as a way to provide foundations for case studies and other small-N studies. As Alexander George and Andrew Bennett (2005) suggest, the idea of process tracing is useful for both development and testing of mechanistic explanations, and it is not the case that only statistical evidence is relevant when assessing causal claims. In general, the debate in political science has been quite similar to that in sociology: the advocates of mechanisms have criticized the simplistic empiricist uses of statistical methodology for ignoring the importance of causal process assumptions in causal inference.

The volume Social Mechanisms (1998) edited by Peter Hedström and Richard Swedberg is comprised of works by many social scientists who have been important in the development of the mechanistic perspective in social theory. The chapters by Raymond Boudon, Jon Elster, Diego Gambetta, Peter Hedström, Gudmund Hernes, Thomas Schelling, and Aage Sørensen represent what has become known as the analytical approach to social mechanisms. This approach has subsequently developed into analytical sociology movement (Hedström, 2005; Hedström and Bearman, 2009; Hedström and Ylikoski, 2010). While it is still developing and important differences exists between its advocates, the approach currently represents probably the most developed version of the mechanistic approach to social theory.

Mechanism-Based Explanation

The idea of mechanism-based explanation has been developed independently among social scientists and philosophers of

biology (Hedström and Ylikoski, 2010). In the social sciences, the idea of causal mechanism has been used mainly as a tool for exposing the unsatisfactory nature of existing theories and explanatory practices, while in the philosophy of biology the aim has been to find a descriptively adequate account of biological explanation. Despite these separate origins and motivations, both traditions are clearly building on similar ideas about scientific explanation. For example, they share the same dissatisfaction with the covering-law account of explanation (Hedström, 2005; Craver, 2007).

In contrast to the covering-law account of explanation (Hempel, 1965), the mechanism-based accounts are explicitly causal. Because of this, they can avoid many problems that have plagued the covering-law account. For example, unlike the covering-law account, the causal theories of explanation do not allow the length of the flagpole to be explained by the length of its shadow. In other words, the causal theories respect the asymmetry of the explanatory relation. The causal requirement also helps with another set of important counterexamples to covering-law account that is based on explanatorily irrelevant information. Thus mechanical approach has a better chance to deal with cases like men eating contraceptive pills and hexed salt that has proved to be embarrassing for the covering-law account (Salmon, 1989; Woodward, 2003). Similarly, the scarcity of real covering laws in sciences like biology, psychology, and the social sciences is not a problem for mechanism-based accounts of explanation. Observable regularities (often called effects) are things to be explained (Cummins, 2000), not the things that are responsible for explanatory understanding. Finally, mechanism-based accounts clearly distinguish between diagnostic and explanatory reasoning. While supporters of the covering-law account propose that the principal difference between explanation and prediction is that in the case of explanation the conclusion of the argument is already know to be true, the mechanism-based account severs the connection: diagnostic effects might allow for prediction, but they are not explanatory, and the sciences provide plentiful examples of explanatory theories that do not allow for precise predictions (e.g., evolutionary theory).

No consensus exists on the right definition of a causal mechanism. Although some theorists find such a situation frustrating, it is not clear that this is a real problem. The entities and processes studied by different sciences are quite heterogeneous, and it might be impossible to propose a definition of mechanisms that would be both informative and cover all the prominent examples of mechanisms. Some disciplines, such as cell biology (Bechtel, 2006) and the neurosciences (Craver, 2007), study highly integrated systems, whereas others, such as evolutionary biology and the social sciences, study more dispersed phenomena (Kuorikoski, 2009), so it is more plausible to think that informative characterizations of mechanisms are field specific. However, it is possible to give some general characteristics of mechanisms.

First, a mechanism is always a mechanism for something; it is identified by the kind of effect or phenomenon it produces. For this reason the characterization of the effect often requires some care. A standard roulette wheel, for example, does not have different mechanisms for distributing the ball to pockets 16 or 17; rather, the same mechanism produces all 37 possible outcomes. However, the effect does not uniquely identify the mechanism: often there are multiple alternative mechanisms for producing similar effects.

Second, a mechanism is an irreducibly causal notion. It refers to the entities of a causal process that produce the effect of interest. Some definitions of a mechanism make unnecessarily strong assumptions, however. For example, it is sometimes suggested the mechanism is sufficient for the effect. This is an all too strong requirement: a mechanism can involve irreducibly stochastic elements and thus affect only the probability of a given effect. Similarly, the requirement that a mechanism should be unobservable (Mahoney, 2001) is a hasty generalization. There is nothing in the notion of a mechanism that would imply that it is by definition unobservable. Most of the mechanisms constituting an automobile's engine, for example, are quite visible when one opens up the hood (Mayntz, 2004). Of course, when one appeals to mechanisms to make sense of statistical associations, one is referring to things that are not visible in the data, but this is different from them being unobservable in principle.

Third, a mechanism has a structure. When a mechanism-based explanation opens a black box, it makes visible how the participating entities and their properties, activities, and relations produce the effect of interest. More metaphorically, it makes the black box transparent. For this reason, the common suggestion that a mechanism is just an intervening variable misses an important point. The focus on mechanisms breaks up the original explanation-seeking why-question into a series of smaller questions about the causal process: Which entities are participating, and what are their relevant properties; how are the interactions of these entities organized (both spatially and temporally); and what changes in the system or in its environment would prevent or modify the outcome?

Fourth, there is a hierarchy of mechanisms. While a mechanism at one level presupposes or takes for granted the existence of certain entities with characteristic properties and activities, it is expected that lower-level mechanisms will explain them. In other words, the explanations employed by one field always bottom out somewhere (Craver, 2007). However, this fundamental status of certain entities, properties, and activities of a given mechanism is only relative, as these are legitimate targets of mechanistic explanation in another field. It is an inherent feature of the mechanistic view that the entities and mechanisms of various sciences are ultimately related to each other. The entities and activities that one theory postulates should be mechanistically explainable by another theory. Although it is sometimes (Kincaid, 1996) suggested that the idea of mechanistic explanation leads to an infinite regress, this is not the case. For a mechanism to be explanatory, it is not required that the entities, properties, and activities that it appeals to are themselves explained. The only requirement is that such entities, properties, and activities really exist; their explanation is a separate question (Ylikoski, 2012).

Finally, mechanisms seem to be combinable. Two or more mechanisms can be combined to form a more complicated one. For this reason, we can distinguish between atomic and molecular mechanisms (Elster, 1999, 2007): atomic mechanisms are the simplest mechanisms analyzed within a scientific field, whereas molecular mechanisms combine two or more

atomic mechanisms. Another way to conceive of the combinatorial nature of mechanisms is to distinguish between causal mechanism schemes and causal scenarios (Ylikoski and Aydinonat, 2014). This distinction captures the fact that there are two different ways to talk about mechanisms. Causal mechanism schemes are theoretically motivated accounts of how certain kind of effect could be produced. These schemes are often rather abstract and they are not assumed to be faithful descriptions of any particular causal process. They basically provide a how-possible explanation; it tells us how an effect of a certain kind could in principle be produced. In contrast, the causal scenarios are meant to be faithful representations of the processes that produce the effect in a particular case. They are often modified adaptations and combinations of more general mechanism schemes. While the fact that both mechanism schemes and causal scenarios are called mechanisms might cause some confusion, their different roles guarantee that neither way of talking about mechanisms is inherently incoherent.

While the notion of mechanism is important in understanding explanatory reasoning in science, one should not assume that it is the ultimate solution to all problems in the theory of explanation. Quite the contrary, the mechanistic theory presupposes accounts of explanatory relevance, causation, and the nature of generalizations that provide the basis for mechanisms. The notion of mechanism should not be treated like a black box. For example, a mechanism-based explanation describes the causal process selectively. It does not aim at an exhaustive account of all details but seeks to capture the crucial elements of the process by abstracting away details that are irrelevant. The idea of counterfactual difference making provides a handle on this process. The relevance of entities, their properties, and their interactions are determined by their ability to make a relevant difference to the outcome of interest. If the presence of an entity or of changes in its properties or activities truly makes no difference to the effect to be explained, it can be ignored. A natural way to understand these causal counterfactuals is to understand them as claims about the consequences of ideal causal interventions (Woodward, 2003, 2008).

Mechanisms and Causation

The idea of mechanism is also often associated with the analysis of causation. Some authors (e.g., Glennan, 1996) have even attempted to define causation in terms of mechanisms. However, it is prudent to keep these two things apart because most characterizations of mechanisms employ causal notions. A mechanistic definition of causation would be circular, and it would face a thorny question about the causal powers of fundamental (physical) entities. If causal relations at the fundamental level are not mechanical, the definition is false, and if they are mechanical, we end up with an infinite regress, which is regarded by many as an unsatisfactory consequence; with the infinite regress there would be no real causation.

The metaphysics of causation is still hotly debated among philosophers, so it is a strength that the mechanistic account of explanation is compatible with a number of different accounts of causation (Hedström and Ylikoski, 2010). However, the mechanistic perspective sets some important constraints. For example, the idea of productive causal activities associated with it implies a commitment to the locality of causal processes; whether A is a cause of B depends on facts about the spatio-temporally restricted causal process, not on what would happen in other similar situations. This means that theories which attempt to define causality in terms of regularities (like Hume's constant conjunction theory, and many probabilistic theories of causation) are not compatible with mechanistic theories. This obviously does not mean that supporters of the mechanistic perspective would have to disregard regularities as an important source of evidence about causal relations.

The relevance of mechanism-based reasoning is not restricted to explanation. Mechanisms also play an important role in the justification of causal claims. Especially in nonexperimental contexts, mechanisms have often play a crucial role in distinguishing true causal relations from spurious correlations. Mechanisms are useful in causal inference in two ways. The knowledge that there is a mechanism through which X influences Y supports the inference that X is a cause of Y. In addition, the absence of a plausible mechanism linking X to Y gives us good reason to be suspicious of the relation being a causal one (Hedström, 2005). Understanding mechanisms is also important in the extrapolation of causal findings. Here the assumption about the similarity of causal mechanisms is crucial for making reliable inferences from one setting or population to another (Steel, 2008).

While it would be too strong to say that mechanisms are necessary for causal inference, a fully satisfactory social scientific explanation requires that the causal mechanisms be specified. In this context, it makes sense to distinguish between simple causal claims and deeper explanatory claims that are based on an understanding of mechanisms. A simple causal claim tells us about counterfactual dependence: it tells us what would have happened if the cause had been different. In contrast, the mechanism tells us why the counterfactual dependence holds by showing what kinds of entities and processes underlie it. One could say that an account of causal mechanism integrates an isolated piece of causal knowledge into a much larger body of knowledge, and helps us to answer many natural follow-up questions about the conditions under which the causal dependence holds.

It is important, however, to emphasize that mechanisms are not a magic bullet for causal inference. In the social sciences, often the problem is not the absence of possible mechanisms, but how to discriminate between a number of potential mechanisms. To avoid lazy mechanistic storytelling, the mechanism scheme must be made both explicit and detailed, and its assumptions must be supported by relevant empirical evidence.

Mechanism-Based Theorizing

The idea of causal mechanisms is also related to broader ideas about the growth and organization of scientific knowledge. According to an old but still influential empiricist view, general scientific knowledge consists of empirical generalizations and more abstract theoretical principles from which these generalizations can (ideally) be deduced. This vision is challenged by

the mechanistic account of knowledge with its emphasis on scientific knowledge as embedded in mechanism schemes and not in empirical generalizations.

According to this mechanism-based view, scientific knowledge expands by adding to, or improving upon, items already present in the toolbox of possible causal mechanisms. Understanding accumulates when the knowledge of mechanisms becomes more detailed and the number of known mechanisms increases. The unification of scientific knowledge, then, consists of developing a comprehensive and consistent understanding of the causal structure of the world. Further, the world studied by the social sciences is complex, so the idea of a unified foundational theory should be treated with great suspicion. It is better to focus on theories of a more limited scope that are compatible with knowledge produced by other fields. Rather than dreaming about grand unified theories, social scientists should develop theories about social mechanisms that are mutually compatible and which form an integrated web where mechanisms at lower levels of organization explain the mechanisms that higher-level disciplines take for granted. For example, psychology explains (and corrects) the assumptions that social scientists make about human cognitive processes.

The above mechanistic vision of knowledge has much in common with Robert K. Merton's idea of sociological theories of the middle range (Merton, 1968). These theories are not just low-level empirical working hypotheses, or all-inclusive attempts to fashion comprehensive accounts of society. Rather, they are focused theories about certain aspects of the social world that can also be applied to other cases. They do not provide a comprehensive description of the empirical phenomenon, but instead capture something essential about the factors that explain it. While Merton's own discussion of theories of the middle range can be ambiguous, the idea of a mechanism-based explanation can be used to make it more precise (Hedström and Udehn, 2009). In the present account, the middle-range theories consist of the causal mechanism schemes discussed above. These schemes are more or less general in the sense that they can be employed and adapted to particular situations and explanatory tasks.

The idea of mechanism-based theories of the middle-range is important in the highly specialized and fragmented social sciences. Although empirical data, research methods, and substantial theories differ from one subfield to another, the general ideas concerning possible causal mechanisms are something these fields could share and thereby mutually benefit from. In this scenario, social theory provides a set of explanatory tools that can be employed in and adapted to particular situations and explanatory tasks. The mechanisms are general in the sense that most are not limited to a particular application. For example, the same type of mechanisms can be used for explaining cumulative advantage in scientific careers, success in cultural markets, and other contexts that are characterized by surprising inequalities in outcomes.

Individualism and Social Mechanisms

A controversial issue concerning social mechanisms has been its relation to the doctrine of methodological individualism. This is no surprise, as some of the most visible advocates of mechanism-based explanations (e.g., Elster, Boudon) have also advocated methodological individualism. Furthermore, as mechanism-based explanations open the black boxes underlying macro variables, they are bound to end up with smaller-scale entities like individuals and their activities. However, as Renate Mayntz (2004) has pointed out, there is no reason to assume that mechanistic thinking automatically leads to explanatory factors that are about the intentional actions of individual agents. Mechanisms that cite supra-individual entities or properties are certainly possible. For example, various filtering mechanisms that are analogical to natural selection are difficult to understand other than as population-wide processes, and when the selected units are organizations (for example, firms), it is natural to conceive of the mechanism as supra-individual. Similarly, it is hard to see how explanations that employ the structure of a social network as a crucial explanatory variable are compatible with strictures of methodological individualism. It, therefore, seems that mechanism-based explanations can refer to a variety of macro facts and processes that are not about individuals and their attributes. More generally, once the idea of there being a fixed and unique 'micro level' in the social sciences is given up, the association between mechanism-based explanation and methodological individualism vanishes. While a satisfactory mechanism-based explanation in the social sciences might refer to individuals, their relationships, and their actions, it is not guaranteed that they would only refer to the individualistically acceptable properties.

Furthermore, the arguments for mechanism-based explanation do not support the assumption that individual intentional explanations have some kind of explanatory privilege. Thus, while Raymond Boudon is expressing a widely felt intuition among methodological individualists when he writes: "When a sociological phenomenon is made the outcome of individual reasons, one does not need to ask further questions" (Boudon, 1998: 177), he is not spelling out an implication of the mechanistic account but rather articulating a doctrine that is in conflict with it. This "intentional fundamentalism" (Ylikoski, 2012) can take various forms, but it is often related to rational choice theory. However, the assumption that human deliberation is a black box that should not be opened is more in line with nineteenth-century hermeneutic romanticism than with explanatorily oriented social science. A mechanistic explanation appeals to micro-level processes, but nothing in the notion of mechanistic explanation implies that these micro things would always be facts about the intentional actions of individuals. Apart from being supra-individual, as argued above, some explanatory mechanisms might also be sub-individual. For example, various biases and heuristics of human cognition (Kahneman, 2011) might have many effects of sociological interest. It would therefore be foolish to limit the explanatory factors available to social scientists to those that can be reconstructed using simple belief-desire psychology. This argument should not be regarded as challenging the claim that there should exist a division of labor between the social sciences and the sciences of cognition. Rather, it points to the boundaries of this division of labor actually being adjustable and not fixed.

The above argument does not imply a denial of the fact that intentional explanations are, and will be, an indispensable part of the social scientific explanatory repertoire. From the mechanistic point of view, intentional explanations are legitimate causal explanations. Furthermore, the intentional attitudes of individuals play an important role in most mechanism-based explanations of social phenomena. The idea of social mechanism in itself, however, does not tell us how to conceptualize human action. Rather than relying on some preconceived ideas about human motivation or cognitive processing, the mechanistic perspective suggests that social scientific accounts of human agency should be based on findings and theories from the psychological and cognitive sciences. So while the idea of social mechanisms is quite often associated with rational choice theory (Gross, 2009), from a philosophical and general sociological point of view the connection between the two is rather weak. There is nothing in the idea of a mechanistic explanation that would require the explanation to be articulated in terms of rational choice theory. In fact, the requirement that mechanistic explanations cite the actual causes of the phenomenon to be explained often makes rational choice explanations unacceptable as they are built upon implausible psychological and sociological assumptions (Hedström and Ylikoski, 2010).

The key idea of mechanistic explanation is that explanation should represent the essential features of the actual causal structure that produces the observed phenomena. Thus it is not enough that the model 'saves the phenomena.' For unrealistic psychological and social assumptions to be acceptable, they must be simplifying idealizations that help the modeling but do not affect the central explanatory relationships in a significant way. This is not often the case in the applications of rational choice theory. However, as gaining an understanding of complex phenomena is only possible in a piecemeal manner, social scientific explanations must abstract away from many details of human mental life. Therefore, only those aspects of cognition that are relevant to the explanatory task at hand should be included in the explanation. In this sense, the explanatory task determines how rich the psychological assumptions must be. So although the mechanistic approach emphasizes the importance of intentional action in the explanation of social phenomena, it cannot subscribe to an axiomatic vision according to which a specific action theory should be used for all purposes. For many social scientific purposes, a relatively simple desire-belief-opportunity model would be sufficient (Hedström, 2005). For other purposes, some version of the pragmatist theory of action (Gross, 2009) could be fruitful.

Future Challenges

The recent work on social mechanisms has been motivated by two broad considerations. First, social scientists and philosophers have attempted to replace outdated philosophical ideas about social scientific explanation with more plausible ones. Thus the criticism of the covering-law account of explanation and associated ideas about causation have received much attention. A consequence of this is that the mechanists have been much clearer about what they oppose than what they advocate. Second, and more importantly, the idea of mechanism-based explanation has been used to advocate improvement in the explanatory practices of the social sciences. For example, analytical sociologists have emphasized the intellectual virtues of clarity and explicitness (Hedström, 2005). Humans are susceptible to illusion of depth of understanding; we tend to overestimate the detail, coherence, and depth of our understanding (Keil, 2003). With its implicit and vague explanatory standards, largely verbal mode of theorizing, and highly complex object of study, social theory is probably a showcase of this failure of metacognition.

The extensive debate about social mechanisms shows that while the idea of mechanistic explanation has been helping social scientists to avoid certain philosophical pitfalls, the mere adoption of loose mechanistic parlance will not fulfill its more important promise of improving social scientific explanatory practices. It has turned out that many things people call mechanisms are basically effects; they describe a certain kind of outcome but do not provide much insight into the process that produces it. For example, when Charles Tilly (2001) talks about democratization as a mechanism, it is quite clear that he is describing something he is interested in rather than giving an account of the cogs and wheels the drive that process. However, the problem is much more general: cumulative advantage, invisible hand, segregation, and self-fulfilling prophesy are all processes that are identified by their outcomes rather than their internal workings.

The future advancement of the mechanistic agenda in the social sciences requires that social scientists develop an increasingly sophisticated theoretical discussion about causal mechanism schemes. In this endeavor, an abstract definition of social mechanisms will be of little help. What is needed is a cumulative work on the exemplars of social mechanisms. Another challenge is development of a methodology for evaluating mechanism-based causal scenarios. Abstract causal mechanism schemes provide the material for alluring explanatory narratives that might be compelling but lack proper empirical support. The basic problem is that in the social sciences, developing sketchy mechanistic scenarios is rather easy; much more difficult is to articulate these sketches into full-blown explanations and finding evidence that discriminates between competing scenarios. Therefore, much depends on the way in which mechanistic ideas are put to use, otherwise social scientists will end up with mere mechanistic storytelling that lacks both theoretical rigor and empirical relevance.

Social Media

Abstract

Social media represent a set of communication practices that can typically be described as 'many-to-many.' In contrast to broadcast media, consumers are typically also producers. In contrast to in-person communication, audiences are often ambiguous or underspecified. These practices have ushered in new forms of political organization and new ways to consider social identity as curated. They have also led to new insights about social networks broadly. Some researchers suggest social media lead to increases in social capital and well-being, while others argue this is at the expense of privacy.

Introduction: Defining Social Media

In some senses all media can be thought of as 'social.' All effective communication requires a sender and a receiver. Recently however, a class of communication practices have been given the moniker 'social media' to demarcate them from other, more traditional, types of media. This term first emerged in popular press (rather than in academic studies) following the dot com crash of 2001, and was initially tied to technologist and publisher Tim O'Reilly's pronouncement of 'Web 2.0' media as being participatory and collaborative. The term subsequently bound itself to almost all online practices involving multiple contributors. Sites that are considered social media range from collaborative encyclopedias such as Wikipedia, to social network sites (SNSs) Facebook and Twitter, photo-sharing sites Instagram, and social news site Reddit. Beyond this, technologies such as instant messengers, and to some even e-mail are considered social media.

With such a variety of media all falling under a single rubric it is difficult to completely map the contours of 'social media.' We follow Hogan and Quan-Haase (2010) in suggesting that there are two key elements of social media: 'many-to-many' communication and nonaddressed audiences.

The notion of many-to-many communication predates social media by a decade, but is conceptually well aligned. This is where people are both producers and consumers of content alongside multiple others. Many-to-many audiences can be contrasted with one-way audiences, where communication flows from content producers to consumers (as in broadcast media) or from large populations to a central authority (as in voting and petitions).

Nonaddressed audiences is a second and significant aspect of social media that distinguishes it from other forms. To be nonaddressed means that the message is not being sent to specific other people, but to some class of people, such as all Facebook friends, Twitter followers, readers of a bulletin board, and so forth. Although the boundaries are fuzzy, one might then consider that an e-mail that is sent to many people with each one on the cc line is not an exemplary form of social media, whereas posting a status update to others is.

We wish to consider these two features as sufficient rather than necessary for identifying social media. But more importantly, these features help to clarify many of the emerging issues and insights from the contemporary social scientific analysis of social media. In general, these issues tend to circulate around idea propagation, identity performance, political mobilization, and large-scale statistical regularities.

The technological infrastructure required to coordinate many-to-many communication between large masses of people tends to be very complex. As such, there is a greater precedent for broadcast and participatory media than social media. And yet we may think of some modest precedents for many-to-many media, such as a town bulletin board or parish announcement board. Given these precedents, we believe that the rise of social media highlights a particular arrangement of communication practices, and not particular gadgets, Web sites, or technologies.

Our focus on the communication practices of social media follows in the vein of medium theorists, such as Marshall McLuhan and Joshua Meyerowitz. However, there have been alternative and often inductive classifications of social media. Kaplan and Haenlein (2012), for example, suggest that each instance of a social media can be classified as one of SNSs, collaborative projects, content communities, blogs, virtual game worlds, and virtual social worlds. Although we find this categorization somewhat retroactive and fragile, it helps to denote that a variety of online media can be considered social media.

In the past decade there has been a great interest in social media from the public. One noted example is the Oscar-winning film, "The Social Network," a semifictionalized account of the emergence of Facebook. But social media has also generated massive interest within academia. This interest can of course be found in the obvious context of ICT-related journals (such as the Journal of Computer-Mediated Communication and Cyberpsychology and Behavior (recently renamed Cyberpsychology, Behavior and Social Networking)), but it can also be found in traditional sociological journals and even within statistics, physics, and maths, where social media generate compelling and challenging behavioral data that are pushing both social and hard sciences forward. Intense academic interest in social media also owes much to the fact that a large proportion of contemporary communication takes place through it, with no sense that this will decline in the near future. Illustrations of the scale of this communication are both staggering and indicative of the embedded, 'everyday,' character of much social media practice (Raine and Wellman, 2012). For illustration, as of this writing Facebook claims

over 901 million monthly active users, and a remarkable 126 billion friend connections. Though far smaller in comparison, Twitter currently claims over 140 million active users and 340 million daily tweets. Research findings have come from both within and across disciplinary boundaries, reflecting the efficacy of multidisciplinary approaches to studying social media.

Below we summarize some of the key debates within social media and indicate some of the foundational advances that have come through the analysis of social media data. In particular, we focus on identity construction, political polarization, the meaning (and uses) of friendship, and the 'laws of the Web' as seen through social media. We conclude with speculation about what enduring future directions for research into social media might look like.

Social Media and Social Identities

Identity Performance and Impression Management

A foundational issue in social media is how to understand self-presentation and online identity. This issue predates social media. As early as 1984, Kiesler identified many of the now-common concerns about flaming, mixed messages, and interpersonal ambiguity now prevalent on social media (Kiesler et al., 1984). Yet, studies of self-presentation go back even further if we broaden our focus to include off-line self-presentation. The symbolic interactionist tradition has been exploring the meaning of identity and the self for almost 100 years, arguably starting with George Herbert Mead. In this tradition (or some might say alongside this tradition), one figure has been consistently applied to identity and social media: Erving Goffman.

Although he had many contemporaries in identity theory, Erving Goffman's work has most successfully endured. Although his work on interaction rituals, stigma, and frame analysis have all been applied to social media, many scholars of social media tend to draw on his early notion of the dramaturgical approach. This approach, introduced in *The Presentation of Self in Everyday Life* (1959) suggests that individuals selectively reveal aspects about themselves in order to live up to some idealized notion of what is expected of them in a situation. Goffman's notion is particularly obvious when people are asked to 'create an identity' on any number of social media platforms.

Using a dramaturgical (or stage play) metaphor, Goffman saw identities as performances whereby people selectively draw upon their own histories as well as their expectations of the current situation and their specific role to play in this situation. Like a stage play, Goffman asserts that interaction has a front stage and a back stage. The front is the public face in any situation and is the site of impression management. The back stage, which is often conflated with private spaces, is where the front is readied.

Goffman's approach lends itself particularly well to the study of user profiles on social media services. Social media's many-to-many quality suggests that individuals are now aware that they have an audience for their content. One is not simply speaking to a specific set of people, but to an audience that consumes one's content alongside the content from everyone else on a platform. A string of theoretical and empirical papers have applied these ideas. Of these, danah boyd's work has been particularly notable for unpacking the idea of 'the audience' of social media content.

The work of boyd primarily focuses on the pressures facing teens of constructing and managing online and off-line identities. Through this focus she has unpacked the many social pressures that come from friending behavior, such as the need to add friends as a signaling mechanism, and the challenge of regulating which friends view which content (boyd, 2007). She reminds us that in contrast to everyday interactions, there is no simple way of articulating the audience for an online interaction on social media. While the audience of a Facebook profile might consist principally of a user's friends, it is not clear in a given moment which friends are seeing (or not seeing) which content. Moreover, since a friend online is merely a signifier for access to content, 'friends' can actually be parents, teachers, bullies, celebrities, workmates, neighbors, and a host of other social roles all in the same space.

In extending, Goffman, boyd, and colleagues have explored the key issue of 'collapsed contexts' in social media. The collapsed contexts of social media, where many disparate roles all have access to the same content lead to both significant challenges for determining what sort of content is appropriate, but also to the continual migration of people between SNSs, and between general SNSs, such as Facebook, and niche sites for subcultures, such as Tumblr and Reddit.

Psychological Approaches to Social Media

To the uninitiated, it may be tempting to think that social media can be separated out into 'good guys' such as Facebook and Twitter, who facilitate Egyptian revolutions and reunite families, and 'bad guys' such as anonymous blogs and image-boards that bully and harass while promoting crypto-anarchism. This is the simplified moral panic of a complex problem related to the tension between collapsed contexts and real-names/pseudonyms. It is based on the folk intuition that without one's off-line identity markers, people are unaccountable and therefore prone to communication that is nasty, brutish, and short.

Early work in computer-mediated communication noted that the absence of the external cues in off-line social situations does tend to foster interaction that is somewhat different than what one might expect. In psychology and social psychology, several theories of behavior have emerged to understand how people adapt to the paucity of social cues online. One, situational deindividuation (SIDE) theory, suggests that while online people experience a sense of deindividuation, and begin to take on qualities and behaviors of the group. Together with several correlates in off-line behavior (such as the 'bystander effect'), SIDE proposes that people really do 'lose' part of themselves online, in response to cues found on the specific site they are using (Joinson, 2002).

The second social psychological theory is the online 'hyperpersonal' relationship (Walther, 2007). This theory suggests that the absence of social cues tend foster a great deal of emotion as people read into whatever scant text is available. Rather than feeling like online text is cold and distant, participants tend to feel a groundswell of emotions over simple short sentences. These emotions can be both positive and negative.

A single nasty comment on a Web site could come from a bitter but harmless teenager or an obsessive stalker. In the absence of other cues, the imagination can be a powerful force in making sense of the bitter comment. The same phenomenon can also lead to strong feelings of community among nonlocal interest groups, where participants may have only said short sentences to each other and never even met off-line. One example is the social news site, Reddit, which now hosts the world's largest gift exchange, has in the past raised millions for charity and holds question and answer sessions with celebrities and politicians alike. President Barack Obama held such a forum ('Ask me Anything') during his 2012 reelection bid.

These rebuttals demonstrate that social media does not need to equate digital participation with off-line participation or online friends with 'real' friends. Individuals can engage in collective action and feel strong emotions solely from their interactions in any given medium. In doing so, they are not merely consumers (or even 'prosumers'), but real political actors in a highly connected world. This has led to one of social media's most active sites of inquiry: the political sphere.

Politics

Among political scientists, there is a growing feeling that old modes and methods of political communication – from elites to the masses (top down) and from the masses to elites (bottom up) – are being rapidly displaced and reconfigured by social media. Activists are building new movements and protests using social media that are increasingly successful at altering mainstream political agendas. In the United States, Members of Congress now routinely turn to Twitter to spar with partisan opponents or broadcast messages to constituents, and use YouTube to post campaign advertisements. In many countries grassroots movements have used social media to affect real policy change in ways that even direct action has failed to achieve. The power of social media in politics is not isolated to the United States, or indeed Western democracies. Commentators have suggested that social media have played a significant part in the organizing of protests and the protection of dissident voices in the popular uprisings associated with the Arab Spring (primarily through Facebook) and the Iranian Green Revolution (primarily through Twitter). The threats that social media presented to regimes have led to efforts of many countries to either crack down on social media, censor content or actors, or introduce surveillance during or after protests. At present, it is not clear precisely what role these media have had – whether it is symbolic, organizational, or merely helpful for the public expression of grievances.

The presence of social media in political action is an active area of inquiry and has generated a host of new concepts to address politics in a network society. One prominent concept is 'the filter bubble' that suggests individuals will have their content curated in such a way to promote like-minded opinions (Pariser, 2011). This sort of feedback loop reinforces much of the political polarization that has been observed in blogs and on Twitter. A second concept is the notion of slacktivism, or the idea that individuals who make symbolic gestures online are in fact engaging in political discourse. Or more specifically, that liking a cause on a social media site can be equated with political action. The most salient case of slacktivism in 2012 was the Kony2012 campaign that sought to oust an Ugandan dictator who was using children in his political conflict. Although it was widely tweeted, viewed online, and shared, little was actually accomplished. This was in part because Joseph Kony did not even live in Uganda anymore and that the problems facing the African nation were vastly more complex than the emotionally tinged video that was widely distributed.

A third concept, crowdsourcing, is one part direct democracy and one part mob rule. Crowdsourcing is sometimes considered a technique for new business models where large masses of people each contribute small amounts to a larger cause, either through voting, expertise, or labor. In politics, crowdsourcing has been used in government consultations as well as investigations into government fraud. It has been used for online petitions, which in the UK at least, has been institutionally approved through Number10.gov.uk. At that site, any petition that gets at least 50 000 signatures will at least get an official response. Also in the UK, crowdsourcing was used to pore over the expenses of members of Parliament to assess whether their expenses were legitimate or not. The newspaper *The Guardian* facilitated this by publishing a quarter of a million documents online to be examined. Social media power these efforts by driving traffic and interest, and providing the coordination to sustain these crowdsourcing efforts.

Each one of these topics has had significant academic and popular treatment, but few have provided strong conclusions about the influence of social media on political movements worldwide. The positive scholars thus focus on the 'social' aspect and the negative tend to focus on the 'media' aspect.

From the social aspect, scholars reflect on the collective power of millions of people adding their voice to a chorus of civic will or dissatisfaction. Anyone can help inform journalism or be a journalist in the right circumstances, and it has never been easier to add one's voice to a political campaign. Cha et al. point this out in *The Million Follower Fallacy* (2010) where they indicate that on globally relevant apolitical topics, celebrities and pundits tend to be the most regarded sources of information. However, in a political event such as the Iranian Green Movement after the contentious election, it was Iranian locals who held the most sway over information. In a more recent piece on the Spanish protest equivalent to Occupy Wall St., González-Bailón et al. (2011) indicate that recruitment into the participatory networks of tweeting did not occur because of a few well-placed celebrities, but due to the slow steady diffusion of many individuals with their own modest sized networks.

When the emphasis is placed on the 'media' portion of social media, critical scholars are interested in pointing out how the infrastructure that facilitates such sociality is not neutral. Instead, the technology itself can be an active agent in filtering, redirecting, and managing the flow of content. Specific to social media, Twitter deliberately curates its top trending topics, with some political topics (as well as pop sensation Justin Bieber) sometimes being excluded. Morozov has written at length about how even when these terms are not filtered, they can still be monitored by repressive regimes who come between a sender and a receiver (Morozov, 2012). This can lead to both active repression of high-profile social media pundits, informers, and scholars as well as passive self-censorship by those who fear someone tracking them. To note, this is not

simply happening in authoritarian countries, but in Western democracies as well. Canadian authorities have used social media to track down individuals who rioted in Vancouver after a Hockey final and the UK authorities have done the same after the high-profile London riots of summer 2011.

Perhaps more pernicious than direct surveillance and monitoring is the passive filtering of individuals into ideologically specific interest groups, with little opportunity afforded for contact between groups. This sort of polarization can happen without any intervention, as was shown in the now iconic visualization of the 2004 American political blogosphere by Adamic and Glance (2005). The image shows two clusters of nodes (blogs), with many links within each cluster (based on who 'reblogs' who) and few links in between. Adamic and Glance sought to demonstrate that there may be completely different blogging cultures online. This situation is vastly different from the world of broadcast news where presenters assumed that their audience would consist of those on both the left and the right. It is more pernicious because this sort of ideological segmentation can be reinforced by algorithms under the guise of 'personalization.' Facebook friend feeds, Twitter lists, and Google results can now be filtered to suit an individual's personal politics even without their explicit consent. On a simplistic level, these algorithms function by noting when a user clicks on more links from their right-leaning friends than their left-leaning ones.

Network Science

Social media are extremely data driven. Outside of antiquated bulletin board systems, social media are very heavily dependent on databases. These large tables of data are searched, sorted, and queried continually. Every now and then, researchers gain access to them for academic purposes. What has come of this is a series of remarkable mathematical insights at the nexus of computer and social sciences. Indeed, much of the findings discussed above come not only from experimental and survey research, but also the use of new methods based on trace data within the emerging field of 'Computational Social Science' (in America) and 'Digital Social Research'/'eSocial Science' (in Europe). Two of these insights in particular have proven robust to the point where their mention in a formal academic context is almost anachronistic. They are 'long-tail distributions' and 'small worlds.'

The importance of long-tail distributions is a substantial challenge to existing normal science. The twentieth century was characterized by the 'normal distribution' – most personalities, heights, weights, etc., tend toward an average or 'mean' and increasingly fewer end up either above or below this mean. The most controversial normal distribution may be intelligence, where it is asserted that most people are of average intelligence with few outliers at the top and the bottom. The Web, on the other hand, is anything but normal. Over 95% of edits to Wikipedia are made by less than 1% of users of the site. Most Web sites receive extremely few visitors, while a small number get millions per day. We must therefore ask ourselves what it means to talk about the 'average' Web site, the average number of edits to Wikipedia, or the average number of sales on Amazon.com. The distribution of these figures is in many cases described as a 'power law' (Barabasi, 2003), but despite this stylish name and rigorous statistical definition it is often more accurately considered as a long-tailed distribution. Though most people communicate with their local friends, there are still celebrities, A-list bloggers, obsessive Wikipedia editors, and so forth who either do far more communicating than everyone else, or communicate with far more people.

In the broadcast era, some people were on television and most were not. But on social media, celebrities are using the exact same platforms as their audience and often in similar ways. It is more the case that, at least in terms of audience, they benefit from a 'rich-get-richer' effect. Those on the top 10 (or the first page) tend to stay on that first page. Hindman (2009) has drawn on this point to suggest that it is not local town papers that are under the most threat from social media, but the middle papers – the state, provincial, and midsize city papers that are being squeezed online by the extremely big players, while the really small players may still find a niche in the long tail.

The second deep insight about social media is that its users are extremely well connected in social network terms. This does not mean everyone has a lot of friends. It means that the whole system can work very efficiently even if people mainly link to their close clusters of friends, as long as there are a few people here and there that link across dense clusters. This property, referred to as the 'small world' phenomenon, is one of the reasons that social media can be remarkably effective at diffusing information (including rumors and scares). The small world phenomenon was originally characterized by Milgram and Travers using a clever experiment involving forwarding letters to an unknown person using friends of friends. Their article popularized the notion that there are only 'six degrees of separation' between people around the world. Watts and Strogatz formalized this property in the late 1990s and early 2000s and found it in many network systems, including social media (Watts, 2002). More recently, Backstrom and colleagues have come up with a rather notable finding. Using the complete Facebook social graph, they have demonstrated that in terms of friendship links on the site, the average number of hops required for one person to know another is not six, but 3.75 or so (Backstrom et al., 2012). That is to say, the average Facebook user can reach any of the 900 million other users on the site using less than four hops *on average*, despite most people on Facebook linking only to off-line and typically local friends.

These patterns characterizing long tails and small worlds are part of the building blocks of burgeoning body of research on how social media diffuse information, cement inequalities, turn on a dime (as people migrate from Friendster to MySpace to Facebook to Twitter to the yet-undetermined-next-big-thing), and simultaneously reinforce the feeling that communication now is both extremely global and extremely local (or what Joshua Meyrowitz and later Barry Wellman termed 'glocalization').

Social Capital, Social Media, So What?

Social media, and SNSs in particular, tend to elicit strong opinions about small design issues. Users criticize Facebook for having a 'like' button, but no dislike button, and Twitter for limiting tweets to a seemingly trivial 140 characters, thereby

dooming them to banality. But one design decision above all has generated seemingly endless editorials, punditry and academic research – the use of the word 'friend' to signify a point of connection. How can an individual have many hundreds or thousands of friends? Do users even know their online friends in 'real life'? In the last half decade researchers have turned this question on its head by suggesting that instead of trying to define what a friend *is*, we should instead look to what social connections *do*.

Increasingly, evidence seems to be that these connections provide support, information, entertainment, and positive self-worth, as well as peer pressure, norms, and expectations of reciprocity. In short, they provide 'social capital.' So, do people feel that social capital exists in social media? A string of studies, but especially those of Nicole Ellison, Cliff Lampe, and their colleagues have demonstrated that in many contexts heavy users of social media do in fact report more social capital (Ellison et al., 2011). Moreover, they have also shown that levels of social capital tend to increase over time for users of SNSs. Other work, such as that of Moira Burke and her colleagues within the Facebook data team, has demonstrated that not all Facebook use is equal. Passive consumption may actually increase feelings of loneliness and exclusion. However, those who actively engage the site, 'like' things, tag, comment, ask questions, and wish others happy birthday tend to report more social capital (2011).

Future Directions for Research

This article has not focused on specific statistics on social media diffusion. These statistics are bound to change, and are difficult to validate in the first instance. We know that most Facebook friends are known off-line, and that the site is the biggest SNS in most countries in the world (with Russia and China being the notable exceptions at present). However, we are not interested in making a story about Facebook exclusively. The key research of the future will not give a better point estimate of how often these media are used, but how eff*ectively* they are used and to what end. A new crop of researchers have emerged to meet these challenges by noting that social media can be a decisive domain for investigating influence, diffusion, social connections, norm formation, and governance alongside a host of recurring and foundational issues around social identity.

Some of the strongest work ought to come from analyses that merge together multiple networks. For example, what is more influential, one's Twitter network, one's Facebook network, or one's e-mail network (bearing in mind the fluid and partial overlap of all three)? But one might also think of networks as bounded by ideology or language. How do different languages influence each other? For example, what sort of content is shared mainly on Weibo (in China) that is not shared on Twitter in English? Additionally, Haythornthwaite's media multiplexity hypothesis (namely that the more media people share the more close they are) could be updated when considering the massive diffusion of potential social media (2005). One might ask: How could we unfilter the filter bubble? Or: How can one rebuild segmented social roles after the context collapse of social media? Finally, if content is persistent and death inevitable, what should become of all the misbegotten profiles?

These questions are relevant whether people are using a desktop, an iPhone, or a tablet. Whether the next gadget is a wristband, heads up display, or a device tapping directly into the brain, it will do little to alter the prevailing notion of social media as a many-to-many practice. The practices themselves (filtering, identity management, curation, polarization, power laws, and small worlds, among many more) will persist. Perhaps in time our understanding will catch up with our technology. In the meantime, social scientists are fully justified in using existing theories of communication. Notions such as medium theory, hyperpersonal identity, impression management, and homophily can be honed, scoped, and elaborated, as researchers compare platforms, users, and practices across the continually unfolding social media ecology.

Abstract

The article on the history of social mobility presents important special terms and discusses the major sources used in this field. It traces the major debates in its history, i.e., the debate on the long-term change of social mobility; the comparative debate on societies seen as particularly fluid, such as the United States; the debates on the change of the gender contrast in social opportunities; and on the change of contrasts in social opportunities between ethnic groups. It finally makes proposals for further research.

General Questions

Social mobility was an attractive theme in the field of social history research during its early heydays in the 1960s and 1970s. Historians explored social mobility with two intentions. First, they wanted to cover the general history of the equality of opportunities in modern societies. Historians were interested in the question of whether the chances for social ascent improved or worsened in modern societies. The increasing openness or growing exclusiveness of the elites, the rise or decline in opportunities for social ascent from the lower middle or lower classes, the developing opportunities for immigrants and ethnic groups, changes in access to channels of social ascent such as education, wealth, family networks and marriage pools, and careers in business, the public services, politics, churches, culture, or entertainment were central topics. Modern societies could appear as particularly fluid, but also as blocked societies. Secondly, historians discussed the history of social mobility in Western societies in a comparative perspective. European and American historians examined the myth of promising opportunities for social ascent and advancement in America as compared with Europe. Historians also investigated the myth of the unblocked social mobility in Communist countries, i.e., in the years after the 1917 Revolution in Russia and also in the years after World War II in the imposed Communist regimes in Eastern and Central Europe. Social mobility was an example of an interdisciplinary historical field, to which historians as well as sociologists and political scientists contributed alike.

In more recent years, other new and basic questions have been added to these initial inquiries. European historians work more on the social mobility of ethnic groups and immigrants, because they became aware that Europe has experienced a major upheaval from being a continent of outmigration to become a continent of immigration. How immigrants succeeded and how their success differed depending on the values and resources of different ethnic groups became an important topic of study for European historians. Moreover the social mobility of women gradually became a somewhat more frequently explored theme, after having been largely neglected in earlier research. These investigations required different methods of research, since occupational careers were less central to women's social mobility for a long time. Finally, international comparisons were less limited to industrial societies in Europe and America, such as Britain, France, Germany, Sweden, or the Eastern United States; Eastern, Central, and Southern European countries as well as non-Western societies were examined more frequently.

Definitions and Sources

Like all fields of research, social mobility research has implicit definitions. Three definitions in the field are most important.

Historians usually investigate social mobility by looking at individuals. Under the heading of social mobility, they usually do not explore the grading up or grading down of entire social groups, i.e., ethnic groups, professions, or entire social classes. The rise or decline of entire families is not examined under this heading either. The Buddenbrook family would normally not be seen as an example of social mobility.

Moreover the research on social mobility focuses on mobility in social hierarchies rather than on spatial mobility. Geographical mobility, i.e., migration, commuting, traveling, and living abroad, is considered a different topic. This does not mean that historians are not aware of the strong influence of geographical mobility on social mobility. Historians explored the relationship between social ascent and migration and the effects of involuntary geographical mobility, such as expulsion or exile, on downward social mobility.

Social mobility research also concentrates on occupational mobility. When historians investigate career mobility (or intragenerational mobility), they usually trace the career paths of individuals, who either moved between different occupations and occupational positions or persistently remained in one single occupation. Historians examining the mobility between generations (or intergenerational mobility) including marital mobility, normally compare the occupation of an individual with the occupation of the father or less frequently with the occupation of the mother and the grandparents. Occupation is usually seen as the crucial and most easily available indicator of an individual in a historical society, though historians are aware that the situation of an individual also depends on other social and economic aspects such as income and wealth, housing and the place of residence, education, and social networks. The historical position and the change of an individual in the social hierarchy is usually explored via occupation. Hence, establishing an approximate

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62022-6

hierarchical classification of occupations is of major importance to historians dealing with social mobility. Upward and downward social mobility is usually measured by these classifications. Still, historians are also fully aware of the problem that the activity of an individual in history, more often in past than the present, might comprise various occupations at the same time, including professions still in the making.

The use of sources in historical research on social mobility also follows a particular approach. Historians link various historical sources and trace historical individuals through sources such as marital records, census materials, tax files and last wills, records of churches and public administrations, and autobiographical sources. The competence of historians in linking these various sources has grown substantially and this makes social mobility studies a highly sophisticated but also time-consuming field of research. Two other trends can be observed in the handling of sources. On the one hand, the secondhand use of sociological surveys by historians has become more frequent and efficient since the latter part of the twentieth century, because access to personal registers in public archives has been restricted due to data protection laws. Quantitative cohort analysis, i.e., research on the differences between the older and younger cohorts in surveys, allows approximate estimations with qualifications about historical trends in social mobility. Important international comparisons are based on cohort analysis. On the other hand, during recent years, social mobility studies have become highly sophisticated. Individual careers are more frequently explored in micro studies with as many details as possible. These studies investigate a number of richly documented individual cases rather than researching all members of a local society through quantitative methods. Micro studies often use autobiographical materials that are difficult to analyze quantitatively and do not allow generalizations. This type of micro study rarely concentrates exclusively on social mobility, but covers a broad variety of aspects.

Four Main Debates

A first debate on social mobility by historians revolves around the increase of social mobility during the last two centuries. There is an optimistic view and a skeptical view regarding long-term changes in social mobility. The optimistic advocates of the rise of social mobility usually argue that not only occupational mobility in general, but also upward social mobility has increased since industrialization. The industrial revolution is not seen as the major dramatic upheaval in the history of social mobility. The more we approach the present, the higher the recorded rates of social mobility. It is also argued that various major social changes have led to more social mobility and also to more opportunities for social ascent: The fundamental changes of the active population from the predominance of agricultural work until the nineteenth and early twentieth centuries to the predominance of industrial work, and the subsequent shift to service sector employment since the 1970s, generated substantial social mobility between occupations. The distinct increase of the sheer number of occupations in all modern societies since the industrial revolution also must have led to more social mobility. The general changes in professional mentalities, a weakening emotional identification with specific professions, social milieus, and also with specific local milieus, and an increasing readiness for job mobility and lifelong training, further enlarged the number of socially mobile persons. The rapid expansion of secondary and higher education especially since the end of the nineteenth century not only had a profound effect on the chances for better training, but also for entry into better paid job positions. The fundamental transformation of societies with very few academically trained persons and a massive majority of elementary school leavers or even analphabets, into societies with various levels of high qualifications and a small minority of elementary school leavers and illiterates, made social mobility and social ascent much easier. The rise of the welfare state, the mitigation of individual life crises, and the guarantee of individual social security clearly improved the chances for further training and for the purposeful use of occupational opportunities. The rapid increase in geographical mobility since the second half of the nineteenth century led to a widening of the labor market and to a greater variety of new chances. The general decline of the fertility rate during the late nineteenth and early twentieth centuries made it possible for parents not only to invest more in the individual support and education of their children, but also to further advance their own professional careers – not only in the case of men, but finally for women also. Changing social differentials of fertility rates also had an impact on social mobility. Equal opportunity policies, i.e., specific government policies aimed at improving educational and occupational opportunities – for lower classes, for ethnic and religious minorities, and later on also for women and for immigrants – also must have had an impact on social mobility. In sum, a substantial list of factors in favor of an increase in social mobility over the last two centuries can be put forward.

The advocates of stagnation or even of a decline in social mobility are a more heterogeneous group. Their arguments stem from very different ideas of social developments. Some scholars who share in the skeptical view, argue that the fundamental upheaval of modern societies during industrialization led to an unprecedented rise in social mobility, (both in upward and downward mobility); and that modern societies thereafter became more closed, since the generation of business pioneers ended and many occupational careers became more formalized and more dependent on formal education; as modern bureaucracies emerged; and as mentalities adapted to the modern, highly regulated job markets. Others hold the view that industrialization in the nineteenth and early twentieth centuries not only led to rising numbers and fundamental change in occupations, but also led to a class society in which the major social classes, the middle class, the lower middle class, the working class, the peasants, and in some societies also the aristocracy, tended to reinforce the dividing lines between social classes and, hence, to reduce rather than to enlarge, the number of mobile persons. Still other scholars discuss the stagnation of social mobility rates in a different and much more narrow sense: They argue that the long-term change in social mobility from the industrial revolution until the present was mostly structural, that is, it depended almost exclusively upon the redefinition of the active population and the professions, rather than on the reduction of social, cultural, and political barriers. According to this view, social mobility

stagnated, apart from the changes simply induced by transformations in occupational structures. Still other advocates of the long-term stagnation of social mobility argue that the educational and occupational chances of lower classes, of women, and of minorities might have improved to some degree, but inequality of opportunities remained, because the middle and upper classes, the male population, and the upper levels of the ethnic majorities did not experience loss of opportunities.

Ever since the beginning of quantitative research on social mobility after World War II, this debate has produced a large number of historical studies of social mobility with a wide range of results. Three main results ought to be mentioned in summary. First, a clear decline in social mobility rates can only be found in rare cases. Most studies show either steady or increasing rates of social mobility, depending on the type of community and country and on the generation and the period under investigation. Secondly, changes in overall social mobility rates do, in fact, depend to a large degree on changes in occupational and educational structures. So in fact, modern societies became more mobile to a large degree because of the expansion of education and because occupational change became so frequent and 'normal.' Finally, there is much evidence that the increase in educational and social mobility of the lower classes and women, did not increase to the detriment of the educational and occupational chances of the middle and upper classes and of men. Except for the Eastern European countries in some specific periods, social mobility was usually not a zero-sum game.

A second debate focuses on the issue of advanced social mobility in the United States and in Communist countries, respectively. The old debate on the lead of the United States dates back to at least the early nineteenth century, when the French social scientist Alexis de Tocqueville argued that American society offered more opportunities for social ascent than Europe.

Various pieces of evidence were presented indicating the American lead in this field. Some empirical studies by sociologists demonstrated that in some crucial aspects a clear American lead could be shown. This was especially true for mobility into the professions. Higher education in the United States was more widespread and offered more chances than in Europe. Hence, the social ascent of people from a lower class background into the professions requiring higher education was clearly more frequent in the United States than in Europe. Furthermore, comparative historical studies on late nineteenth and early twentieth centuries American and European cities showed that in particular cases, America was in a modest lead during this period: Unskilled workers in fact moved up into white-collar positions in American cities somewhat more frequently than in European cities. Finally, historians demonstrated that the important difference between American and European societies could be found in the American creed that the United States offered greater opportunities than the more closed European societies.

Other recent comparative studies tend to argue that American society is no longer in the lead in comparison with Europe. According to this view, industrialization and modernization led to similar opportunities everywhere. Various international comparisons of social mobility rates support this view and demonstrate that the overall rates were not distinctly higher in the United States than in older societies such as Western Europe or Japan. As these comparisons deal almost exclusively with the second half of the twentieth century, the results might be due to the fundamental social changes in Europe and Japan since World War II.

The opportunities for social advancement in Communist countries, especially in the USSR, during the 1920s and 1930s and in the Eastern European Communist countries in the late 1940s and 1950s are at the center of a less intense but important debate. Some historical studies of social mobility demonstrate that during these periods, rates of upward social mobility into the higher ranks of the social hierarchy in these countries were substantial compared with Western European societies. This was true partly because of the rapid expansion of higher education, partly also because of the Communist abolition or even physical extermination of the urban and rural middle class and partly because of far-reaching changes in the employment structure as a result of rapid industrialization enforced from above. However, the rise of social opportunities in Communist countries was, if it rose at all, largely limited to the period of their early beginnings. Most comparative studies of the 1970s and 1980s show that rates of social mobility were not distinctly higher in Eastern Europe than in Western Europe. This was partly because the Communist political and administrative elite became exclusive and gentrified, partly because social change slowed down, and partly because the expansion of higher education was reduced in several Communist countries.

Only a small number of historical studies have examined gender-related differences in social mobility. A comprehensive debate among historians has yet to develop. But gender differences might add new important aspects to the general debate about long-term trends in social mobility. Four conclusions can be drawn from the few studies that exist. First, in a more radical sense than in the study of male mobility, female mobility raises the question whether social mobility should in fact be centered around occupational mobility or whether other factors – such as marriage and unpaid or partially paid work in emerging professions – deserve much more attention. Secondly, the question of whether there was an increase in downward mobility during the transition to modern society, (i.e., during the rise of female activity outside the family sphere) is to be explored. A study of female social mobility in twentieth century Berlin demonstrated a high rate of intergenerational downward mobility among active women during the early part of the century. Thirdly, the studies on the social mobility of women clearly demonstrate the effects of economic crises and fundamental transitions on social mobility. Opportunities for women seem to have depended strongly on economic prosperity and on long-term social stability. In periods of economic crisis and rapid transitions such as the upheaval of 1989/91, more women than men were among the losers. Here again the study of female mobility might draw the attention of the historians to a more general aspect of mobility which requires further investigation. Finally, social mobility of women also demonstrates that definite changes of social opportunities were only reached in a long-term perspective. It was shown that even when important channels of upward social mobility such as education offered equal chances to women, this did not immediately lead to better

and more occupational opportunities for women. Besides the study of institutions and policies, the historical study of the experience and perceptions of social mobility is crucial.

The debate over long-term changes and international comparisons of the opportunities of ethnic groups in the nineteenth and twentieth centuries has also not yet fully started in general terms, in spite of numerous studies on individual ethnic groups. Whether the chances of social ascent for the Italian, Polish, Jewish, Irish, or Finish immigrants in the nineteenth and early twentieth centuries in France, Germany, Switzerland, Britain, and Sweden compared with the indigenous lower classes, were in fact clearly worse than for the Italian, Spanish, Portuguese, Yugoslavian, Greek, Turkish, and Maghreb immigrants in the industrialized West European countries since the 1950s in comparison to the new lower classes, and also worse than for the new immigrants since the 1990s into Southern and Western Europe, has not been examined so far. It is also not clear whether the chances for well-educated middle class immigrants to enter the various national middle classes in business, the sciences, entertainment, and culture in Europe, improved in the late twentieth and early twenty-first centuries, compared with the nineteenth and early twentieth centuries. Did a German middle class immigrant in liberal nineteenth-century Britain actually have less opportunities than a French middle class immigrant into the highly regulated late twentieth-century Germany? We implicitly assume that European societies gradually offer better chances for immigrants, since this has increasingly become a major issue in politics, in the media, and in scientific research since the 1970s. But precise comparisons in time and space have yet to be made.

Future Historical Research

Since the 1980s, social mobility has been less frequently studied by historians in Europe and the United States, with the exception of Dutch historians. The topic became less attractive, because historical change appeared to be less spectacular than had originally been assumed and also because international differences did not seem very intriguing. New research on social mobility did not look promising. Moreover, the standards for historical research on social mobility became so high and the access to archival material became so restricted because of data protection, that historians were discouraged.

Still, the history of social mobility offers a range of new questions besides the topics that have already been mentioned. International social mobility, i.e., the rising international paths of careers (especially of highly qualified persons), is one of these new topics. Working abroad for a certain period or one's entire life, often combined with an international marriage and careers supported by international families or in international organizations, is a rather recent development. But international social mobility always existed in history in large organizations such as the churches, in the European courts, among European artisans, and in outmigration from Europe during European expansion. The long-term historical continuities and the major upheaval of international social mobility pose a new challenge for historians. International historical comparisons of social mobility, which have always been of major interest but strictly limited to the Western sphere, are a second challenge. Expanding international comparisons by including other regions of the world, especially the new economic powers in East Asia, India, Latin America, and Russia and the study of the effects of the various globalizations will give social mobility research a new attraction. Moreover, a crucial element of the new poverty in industrial societies (the poverty of single-parent families, immigrants, drug addicts, broken careers) is seen in the almost total lack of opportunity to leave this new class of the precarious poor and achieve at least lower middle class status. Study of the extremely limited opportunities of this new class of the poor and its resemblance to older historical poverties in respect of social mobility, is a further challenge for historical research. Finally, historians are perhaps more open and more prepared to investigate change in representations of social mobility in government policies, in elites, among those who promote the channels of social mobility, and also among the mobile individuals themselves. This is a topic on which historians have a chance to be read attentively, also in other disciplines.

Abstract

The purpose of this article is to provide an overview of the ways in which political violence and social movements connect, as well as of the ways in which these connections are studied in academia. It delineates and expands on three specific topics: the emergence of political violence, the disengagement from it, and the consequences of it. The reviews of violence emergence and disengagement are broken down by the level of analysis into macro, meso, and micro; the review of the consequences of violence is broken down into the political, economic, social, and biographical areas. At the conclusion of this article, we offer brief remarks on the field's future directions.

There are two facets to the issue of social movements and political violence. The one facet regards the phenomena to be studied, namely phenomena of social movement-related violence. These phenomena include violence by social movement members as well as violence against them. They are therefore wide-ranging, covering anything from protest by throwing food at politicians to protest by categorical killing, and from police control of street protest to state-approved torture, to mass killing of movement constituencies by militaries. The other facet regards the academic fields that study these phenomena. One field that does so is, of course, the field of social movement studies. But there are other fields, too, and among them the most visible – indeed much more visible and influential than the field of social movement studies – is the field of terrorism studies.

Thus the subject matters of the fields of social movement studies and of terrorism studies often overlap. (The former field predominately studies social movements outside the context of violence; the latter field on principle covers also violence which is unrelated to social movements.) As the two fields approach their common subject matter, however, two differences stand out. The one is theoretical. Social movement studies bring to their investigations of violence the field's standard theories and concepts, rather than developing separate ones particular to violence. In general, the social movement approach has evolved from a structural orientation, characteristic of the 1970s and 1980s, to the so-called political process approach dominant from the 1990s onward. Reflecting the influence of American sociology, the political process approach privileges organizational and relational analysis. It therefore locates political violence within the context of social, political, and cultural conflicts, and considers the turn to violence as being part of broader processes of political contention (Bosi et al., 2014). On its part, the field of terrorism studies has been mainly dominated by security questions – security of the public and/or the state – and has often produced policy-oriented knowledge (Goodwin, 2004). Stemming from a long tradition in political science concerned with a residual category of political violence resultant from the exclusion of interstate warfare, this field has privileged the theories and analytical perspectives dominant in political science. These perspectives, though varied, have in general eschewed the literature stemming from the field of social movement studies, though this has been less the case in recent years. The second outstanding difference between the two fields is conceptual, or more precisely, one about labels. Social movement studies avoid the usage of the label 'terrorism' (as well as the related 'terrorist' and 'terror') while obviously the field of terrorism studies thrives on it. For social movement scholars, this label is too political – a tool which sides in a contention employ to degrade their opponents (Tilly, 2004; Porta, 2013). While all labels (and terms) are value-laden, this particular label, the argument goes, is so heavily political that it is impossible to use it in neutral terms. While differences on theory and labels separate the two fields, however, it must be noted that a relatively small body of scholarship claims a position in the middle. This is the scholarship that utilizes both the term 'terrorism' and the analytical tools and theories of the social movement field of study.

The exposition that follows focuses on three areas of inquiry: the emergence of social movement-related violence, the disengagement from it, and the effects of it. This exposition is predominately concerned with the field of social movement studies, and this is done mostly out of reasons of economy. The literature that directly or indirectly refers to social movement-related violence is immense, including not just terrorism studies but also approaches to social conflict that range so widely that practically touch on all divisions in the social sciences. Only with regard to the first area of inquiry, on the emergence of violence, do we engage in a more comprehensive discussion. Given that this is the most researched area with respect to social movement-related violence, we juxtaposes insight from the field of social movement studies with insight from the field of terrorism studies. The other two areas of inquiry are far less researched and so we devote less space to them below.

The Emergence of Political Violence

Most of the attention of the field of social movement studies concerned with questions of political violence has been on its emergence. This attention covers both violence by social movements and violence by the state, in contrasts with the field

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96040-9

of terrorism studies, which tends to ignore state violence (unless it is counterterrorism).

Macro Level

A tradition of explanations of the emergence of social movement-related violence exists among mainstream terrorism studies at the macro level of analysis. In this line of studies, attention is placed on conditions that are external to the perpetrators of violence, which is to say, environmental conditions. These are considered to be root causes or permissive factors, setting the stage for political violence to emerge. Accordingly, such causes or factors are sought in the international system, the political culture, or the economy and other material conditions. While these causes/factors are often treated as conditions – hence structural elements affecting the likelihood for violence – processes are sometimes evoked too. In these instances, the processes typically regard modernization, sometimes its advance but more often the interruption of its advance. Either as structural conditions or as processes, these explanations betray a bias of focus, as they eschew state violence. Typically, attention is placed squarely on the populations outside the state that use or may use violence against the state. Hence environmental conditions create 'populations at risk,' as per an often-used label: the international system is said to create dominated and indignant populations, the economy populations with grievances, material factors deprived populations, political culture belligerent populations, and so on.

Guided by the positivistic epistemology that characterizes much of political science, especially of earlier years, these conditions are often presented as building-blocks to theory by way of discovery of necessary (sometimes even sufficient) conditions. While thought-provoking in their attempts to single out some root causes, however, neither one nor any combination of these conditions can be recognized as necessary (let alone sufficient). The evidence does not allow this; political violence clearly occurs in rich as well as in poor regions, in modern industrialized countries as well as in less developed ones, and so on. Indeed, despite the long line of research in macrolevel terrorism studies, no general theory has emerged to claim wide scholarly adherence. In fact, if one gives this scholarship a careless reading, one can easily be misled. For as Tore Bjorgo writes, the "limitation of the 'root cause' approach is that it may give the impression that terrorists are merely passive objects of social, economic and psychological forces: puppets obeying what these causes compel them to do" (2005: 3). Still, considered through nonpositive epistemology, this scholarship can be recognized to have enriched the understanding of the environments fostering violence.

The social movement approach has offered only a partial alternative to the search for macrolevel conditions characterizing some terrorism studies. It is a partial alternative because usually – though not always – it is not exclusively a macrolevel approach but rather an approach combining the macro and meso levels, and sometimes the micro level as well. The early collective action models that paid attention to the macro level were structural – hence hardly alternatives when epistemology is concerned. In particular, much of their attention was on the investigation of political opportunity structures, usually understood in terms of power configuration. But as structural models gave way to models of political process, attention turned to dynamics that connect different levels of analysis. Charles Tilly is one of the protagonists in this development, advocating and applying a systematic and multilevel exploration at the intersection of political violence and collective action. His approach, like much of the contemporary social movements approach, is organizational and relational, which means that chains of relations are treated as the 'glue' holding the various levels of analysis together (Tilly, 1998, 2003). In this approach, the causal dynamics are expected to be varied and even heterogeneous, though typically relational. At the macro level, they generate such figurations as those defining political fault lines and identities as well as power-asymmetries, which is to say figurations which are also articulated at the organizational meso level.

Just as with its epistemological scope, the social movements approach has a broader empirical scope than terrorism studies. Specifically, social movement scholars have been more ready than terrorism scholars to include state violence in their studies. Some, like Tilly, advocate the application of the same analytical tools to the study of both state and antistate violence. Others fix their focus on empirical studies of state violence. From these studies, in fact, a growing tradition of macroscopic research on state repression has developed (Porta, 1995). Thus, for example, one brunch in this tradition is concerned with historical patterns of policing protest, and another with the institutionalization of police autonomy.

Meso Level

Mainstream terrorism studies have developed a tradition in mesolevel analyses as well, focusing at the level of the group waging violence. Two distinct approaches have dominated this tradition: the ideological perspective and the instrumental perspective. The first approach tends to define armed groups as ideology-driven conspiracies against the political system. The members of these groups are considered to be attached to ideological precommitments, and their action is explained in terms of clashes of ideology or through ideology's role in recruitment, popular support, activism, selection of tactics, and so on. The second approach considers the members of armed groups to be instrumental actors, hence recognizing them the same capacity for rational choice as it is presumed to characterize all other political actors. The action of these groups is therefore explained through political and tactical calculations connecting means to ends. Whereas the first approach implies that devout adherence to ideology erases or reframes possible scruples regarding the use of violence, the latter approach assumes flexible end-game preferences of which violence is dispassionate calculated means.

These two traditions in terrorism studies are often considered contradictory to each other. In a sense, however, they are similar. For in both of them the primary unit of analysis relates to the realm of mental, cognitive operations. By contrast, the epistemology of the social movements approach tends to be both broader and more attentive to organizational analysis. This approach, therefore, may be open to the analysis of cognitive operations – typically through frame analysis or other cultural analysis – but includes organizational analysis as well.

Social movement strategy formation is a central subject matter that is usually placed under comprehensive analytical frameworks. Organizational analysis, on its part, often distinguishes three areas: the social movement organization, the social movement, and the social movement context. Regarding the social movement organization, the analysis can focus on the structure of hierarchy, the form of decision making, organizational resources, and so on. Also of interest in this area of analysis are issues relating to the clandestine character typical of violent groups; this is a differentiating characteristic vis-à-vis nonviolent movement organizations and can therefore be a point of comparison between violent and nonviolent contention (Zwerman et al., 2000). Regarding the social movement, the analysis typically pertains to the relations among the social movement organizations comprising the movement. These are often competitive relationships – over resources, popular allegiance, division of labor, and more broadly power (Alimi et al., 2012; Demetriou, 2007). In terms of violence, and in particular the switch from peaceful to violent tactics, analysis in these two areas may reveal consequential organizational splintering. The creation of the Provisional Irish Republican Army (PIRA) out of the ranks of the Irish Republican Army is an example of splintering at the level of social movement organization, and the creation of the Red Brigades out of the Italian Left movement is an example of splintering at the level of the social movement; in either case, the splintered organization proved particularly violent. Regarding the social movement context, too, the analysis can be, as it often has been, fruitful. For here one can examine the resources, opportunities, and constraints facing the movement, as well as the relations between the movement and interested publics or the state authorities. To appreciate how pregnant with consequences these relations are, just consider the last one – the relation between the movement and the authorities. This relation may take the form of repression by the authorities which research has shown to be an important factor in instigating political violence. Especially when the repressive measures appear to be hard, illegal, or confrontational, they may delegitimize the state and encourage antistate hostility and sympathy for armed groups (Porta, 1995; Wood, 2003). For example, the activities of the nationalist insurgency in Ireland in 1919–21 were often met with brutal reprisals by the state security forces, aimed at populations perceived as hostile; given that the main goal of the insurgency was the delegitimization of the state, the state through its tactic of reprisals was in effect doing the insurgents' bit (Demetriou, 2012).

In short, the meso level of analysis is the quintessential level of organizational analysis and the one through which social movement studies have thrived. To be sure, not all studies on violent social movements pursue as comprehensive organizational analyses as suggested above, but the developing trend is toward comprehensiveness (e.g., Alimi et al., 2012).

Micro Level

At the micro level of analysis, the main quest of terrorism studies is toward the understanding of the motivations of the activists engaging in violence. This follows a more general tendency, common outside social scientific academia and within the circles of policy-makers interested in counterterrorism, to offer motivation-type answers to the question "Why action happens?" A rich tradition therefore exists offering psychological explanations of the resort to violence. Reflecting an interest with rational choice theory, some scholars in this tradition bestow the motivation of greed on the activists whom they study. Combined with the activist's instrumentality, greed is therefore said to explain the choices in careers in violence. Other scholars in this tradition hold grievances to be the prime motor of motivation, while still others expand the pool of motivations to cover emotions, including emotive reactions to material conditions. Still other scholars develop violence-prone personality theories, variously privileging such psychological patterns as dependency, circular reaction, or the seeking of identity. Implicitly or explicitly, much work in this latter research agenda treats political violence as psychopathology.

Within social movement studies, the tendency is not to engage in microlevel analysis in isolation from broader analysis (Bosi and Porta, 2012). Here exists as well, however, a long-standing interest in the study of activists' motivations. A body of research covering activists' narratives exists in particular, though given the practical difficulties associated with interviewing active perpetrators of violence, these tend to be distant *post factum* accounts by ex-activists. But where the scholarship goes beyond the mere representation of the activists' voice, as it often does, then broader analysis is engaged in order to draw conclusions on collective behavior. Thus such standard analytical modalities as the examination of opportunity structures, of in-group and ramified relationships, and of framing are broad into the equation. Indeed, social movement research repeatedly demonstrates that the individual choice to join an armed group is better explained as collective choice. Thus, it is demonstrated that preexisting social relationships tend to influence greatly individual decisions to join armed groups. Also, it is shown that small networks of people with dense ties with each other (family relations, group of friends, school, local community, and so on) tend to progressively justify the need to use violence and through this they feel less responsible as single individuals (Bosi, 2012; Viterna, 2006; White, 1989).

The Disengagement from Political Violence

What disengagement from social movement-related political violence may mean exactly is open to interpretation. Phenomena of disengagement from violence have affinity with phenomena of political deradicalization and of cycles of violence – after all, it is often the passage of time that tells definite disengagement from temporary disengagement. Thus social movements scholars can, as they often do, study these phenomena indiscriminately (Fillieule, 2010). Nevertheless, a literature on disengagement from political violence does exist as such, and it tends to focus on marked behavioral modification on the part of militants or armed organizations. In this sense, disengagement does not imply necessarily change in values or ideals, but clear change in the means of contention (Bosi, 2013).

Macro Level

Given their clandestine character, armed groups and activists tend to progressively isolate themselves from the world around them. This may lead them to increasingly supercilious interpretations of their role in politics, highlighting the wisdom of their actions and the follies of their opponents. Still, these activists are never totally disconnected from the world. Armed groups are always and inevitably immersed in the conditions of their environment. There is therefore reason to study the environmental conditions that affect the likelihood for armed groups' disengagement from violence. In general, such conditions may relate to the closing of political opportunity for the groups or for the movements in which the groups are part, and to the falling supply of the elements that are vital to the survival of the group (membership, armaments, funding, and so on) or the movement (public support, alliances, and so on). What needs to be underlined regarding this course of macrolevel inquiry is that the focus is not so much on the activists' attribution of environmental changes (which may elude research, if it is done in real time) as on an objective assessment of these changes.

State repression is particularly important for the evolution of armed groups, since it can present a barometer of sorts for the political opportunities at hand. However, the available body of research does not offer strong evidence to suggest that repressive policies on their own lead to disengagement from violence. But then again, any isolated environmental condition carries limited efficacy in explaining (or forecasting) disengagement. Combinations of macro factors are more efficacious explanans. But more efficacious still are macrolevel analyses that are combined with mesolevel analyses. This is so because macrolevel analyses may account for the likelihood but not the timing of actual disengagement, where timing is typically analyzed through meso lenses. Thus a repressive policy needs to be analyzed in connection with its timing, which is to say, as a matter of conjuncture more than structure.

Meso Level

At the meso level of analysis, research can turn to an array of factors, emulating research done with regard to the emergence of political violence. Indeed, one may expect to find that the reversal of mechanisms precipitating violence may precipitate disengagement from violence. As noted at the introduction, however, the body of research on disengagement is rather limited, at least within the social movements literature. To the extent that one can talk about directions forming within this body or research, one can note an emerging attention to armed groups' strategy.

It is not a forgone conclusion that the use of political violence is met with public criticism. In legitimate polities, however, the likelihood that this may happen vis-à-vis antistate violence is high. In these situations, armed groups may find themselves in crossroads necessitating the adjustment of their strategy. Thus, on the one hand, they may opt to further distance themselves from public, including potentially their own constituency, by 'purifying' their stand in order to sustain activists' commitment in the face of increased adversity. On the other hand, they may opt to become more receptive to public opinion and the pull toward moderation which public opinion may represent, especially if this opinion comes from the movement constituency. Whereas the former outcome would lead to the increase of violence, the latter may lead to a progression away from violence. Facing choices such as these, armed groups are constrained by both external dynamics (political opportunities and public support) and internal dynamics (resources and intragroup dissent), all of which are complicated. The pathways toward or away from disengagement are therefore open-ended. For example, groups weak in material resources may react to opposition from their environment by further radicalizing their tactics, since this may shore up their organizational integrity. This may then accentuate group isolation to the point of the group becoming a sect, out of touch with political reality, and provoke revulsion among its actual or potential constituency. Such developments, in turn, may lead to defections from the group, which is to say, individual disengagement from political violence. This, in its turn, may lead to group disengagement form violence, further radicalization of tactics by the group, or group split. Relevant in this sort of dynamics, moreover, is the state counterpolicy, including counterviolence. The course of the movement–state interaction, too, is open-ended. Heavy-handed state policies, for example, certainly influence the course of contention, but not in a preordained direction: they may weaken or strengthen the resolve to antistate violence, reduce or enhance popular support, and so on.

Micro Level

To the extent that microlevel analysis is considered to pivot on psychology, disengagement from violence implies turning points in personal histories whereby commitments, emotions, and rationales change. A psychological barrier needs to be crossed. Typical of the social movements approach in general, however, psychological factors are here examined in relation to collectivities and their environments. Hence the attention is not so much on personalities and other attributes of individuals, but on the interactions among individuals, such as the breaking up of strong ties of friendship, loyalty, and trust. Projection on the future is relevant, too, and so the risk of social isolation can be a pivotal factor in 'changes of heart.' In other words, according to this line of analysis, maintaining or abandoning commitment to political violence depends on the emergent social psychological price entailed in the alternatives.

As with dynamics at the mesolevel of analysis, however, dynamics at the microlevel of analysis are not considered deterministic. Thus, for instance, if activists develop the view that old-standing violent tactics are no longer justified in the face of new political developments, this does not mean that they are able, or even willing, to disengage. Feelings of belongingness, the incapacity to see another possible future apart from that in the armed group, and the fear to live with the bad consciousness of having believed in wrong ideas, all may prolong activists' participation in armed groups. Indeed, perhaps the single most efficacious predictor of individual behavior is collective behavior – individuals would more likely commit to drastic change in their behavior if they do so in company.

The Consequences of Political Violence

The research within social movement studies on the consequences of violence is lacking behind the research on disengagement – let alone that on the emergence of political violence. This scarcity of research is striking if we consider that the purpose of the use of violence against the state, or by the state against social movements, is typically to elicit or prevent change. It is all the more striking given that the range of targets is wide. Antistate violence tends to target agents of the state, and violence by the state tends to target agents of social movements. But the two sides also aim at proxy targets – businesses, the media, constituencies – either because they are symbols, knots of power, or simply available. As with the literature examined above, the available social movement literature on the consequences of violence is skewed toward the study of antistate violence. Within the limits of this bias, however, the literature brunches out toward four areas – the areas of the polity, the economy, the society, and biography (Bosi and Giugni, 2012).

Political Area

While political violence typically affects policy, the magnitude of policy change may range greatly. On the one extreme, the change may entail the transformation of the state itself. Historically, this has been especially the case with regard to separatist movements, and the wave of decolonization in the 1960s offers many acute examples. Even separatist movements that fail their ultimate goal may precipitate the limited transformation of the state. For example, partly as a consequence of the campaign by the group Basque Homeland and Freedom, a considerable measure of autonomy was granted to the Basque region (Herrera, 2002). On the other hand, violent political contention may produce what from the claimants' point of view are negative, regressive effects. The massive and essentially permanent dislocation of Kurdish populations in the eastern part of Turkey by the government during the 1980s, designed as a response to the campaign of the Kurdistan Workers' Party, offers a prominent example of this.

More modestly, the effects of violent political contention may regard anything from public order policy (censorship, the banning of organizations, etc.) to legislative outputs (legislation as well as change of legislative procedures), to executive outputs directed at various targets including the armed groups' constituencies. These policies may outlast the campaigns of violence. Public order policy, typically aiming at treating the effects of violent political contention, may remain in effect permanently. Forms of policy aiming at the perceived causes of such contention may as well have long-lasting effects. For example, from 1972 onward and through the 1980s, the UK government made efforts to redress some of the grievances of the nationalist community in northern Ireland with the hope of undermining the campaign by the PIRA. But as it turned, the general direction of this policy, which included fairer hiring practices in the public sector and electoral reforms, has been the same as that which the Good Friday Agreement of 1998, ending the campaigns of violence, has promoted (Bean, 2007).

Economic Area

Violence obviously affects negatively the economy of the relevant state. It can damage property, prevent the use of capital and movement of goods, cause inflation and unemployment, and more generally inhibit economic growth or bring about outright depression. These effects can have negative regional or global economic ramifications, though the reverse might also be true – e.g., the loss in the tourist industry of a conflict-ridden state may be the gain in the tourist industry of a neighboring state. Analysis can distinguish between direct effects in the short run – including economic effects relating to increased medical provisions as well as to the direct loss of property and the like – to less direct effects in the long run. The latter sort of effects, typical of protracted violent political contention, may relate to anything from the deterioration of the health and educational systems to the loss of workforce through changes in migration patterns. In general, it can be said that the effects of political violence on the economy are negative but not all sectors are affected equally, while some sectors – notably those providing security services, infrastructure, consultancy, or news coverage and commentary – may benefit.

Social Area

The scope of social change resultant from the use of social movement-related violence is very wide indeed, while the direction of change is not preordained. Obviously the intensity, spread, and duration of violence are factors making a difference, and certain changes are expected to follow certain types of violence – e.g., emigration to follow intense violence against a population. Still, the direction of social change can vary. For instance, the levels of social trust or social integration may be reduced in the face of the dangers associated with the use of violence. Yet, at the same time, opposite phenomena may transpire vis-à-vis segments of a population. Thus the use of political violence may increase communal identification and improve the morale of discriminated communities. This seems to be the case, in fact, for many Muslims in Europe, especially of younger generations, who feel empowered by radical Islam, even when they condemn political violence in the name of Islam (Roy, 2004).

Nor are the patterns of public opinion transformation clear. Amid political violence, the prevailing change in the short run may well be the polarization of opinion. But in protracted conflicts, this direction of change may not hold. For example, some of the long-term effects of the Palestinian armed campaigns in the occupied areas in recent decades (the Intifadas, the Tanzim movement, and the campaigns by Hamas) point to the direction of moderation. According to one study, these campaigns contributed to the evolution of the political orientations of local populations by increasing their willingness to accept a Palestinian state and make territorial concessions, and by decreasing right-wing identification (Gould and Klor, 2009).

Biographical Area

The effects of violence on those affected by violence is, strictly speaking, a subset of what has just been discussed – i.e., effects

in the social area. But these effects also present an area of study offering particular insight on broader issues of social movement-related violence, not the least the question of disengagement. On the one hand, under study can be former activists, that is, individuals who had perpetrated violence. Even at low levels of activism, these individuals may face life-long consequences. An elementary yet important question is whether they honor or denounce their old commitments. Postconflict settings show that both sets of individuals are likely to be present and to complicate even more the political tangle associated with efforts at 'truth and reconciliation' – not just issues pertaining to the revision of the meaning of one's life, but also ones pertaining to culpability, punishment, and social closure.

Further, the victims of violence and those related to them may likely face life-long consequences. Much of what said above regarding postconflict contexts applies here too, including the broader question of how the personal experience and the collective experience are linked. Trauma, for example, has both a personal and a collective dimension, becoming in interconnected fashion a point of reference for both the victimized individuals and the communities in which they belong. The social movement literature only made limited inroads in this direction of research, despite the fact that this literature's rich insight on the interconnection between individual and collective action offers a spring board. Of course, the broader literature concerned with questions of victimhood and conflict – in psychology, social psychology, collective memory studies, and so on – is rich and also offers examples for the social movement scholars to emulate.

Future Directions

It is seen that the field of social movement studies has made gains in the area of violence, especially regarding the emergence of violence. At the same time, it is clear that biases and lacunae also exist in the field – i.e., more attention on social movement violence than on state violence, and insufficient attention on the disengagement from violence and on the effects of violence. Moreover, it is seen that the inquiries in the field are also pursued by other fields, especially terrorism studies, with divergent results.

Two opposing cases can be made for the future of the investigation of social movement-related violence. The one is in favor of pluralism. According to this position, the existing pluralism among the different fields in terms of theories and analytical frameworks is healthy and must be safeguarded. The other case is the opposite. That is, this pluralism is not healthy because it is the result of lack of knowledge across the fields and the academic disciplines which, to some extent or another, align with the fields; the pluralism must therefore be replaced by more unifying sets of theories.

Current trends exist in both directions. The present pluralism is sustained not so much by the intension of the participating scholars as by factors having to do with the general organization of academia; the overall trend is therefore toward the inadvertent perpetuation of pluralism. At the opposite end, various scholars promote broad analytic frameworks intended for research in different traditional fields. The 'Contentious Politics Approach' is the most prominent result from this kind of efforts. Promoted by scholars in the field of social movement studies – Charles Tilly, Sidney Tarrow, and Doug McAdam, among others – the approach argues that the delineation of research according to the concept 'social movement' (as well as 'terrorism') must give way to delineation according to the concept 'contentious politics' (McAdam et al., 2001). This concept is meant to denote any contention outside the formal channels of government. It therefore covers a broader category of phenomena than the category 'social movements,' including episodic contention by way of labor strikes and ethnic conflict. The advocates of this approach hold that such a wide range of forms of contention can be analyzed through a coherent analytical framework, thus allowing comparisons among phenomena which traditionally have been considered incomparable.

Further work is needed before this and other similar approaches become mainstream and replace more specialized fields; indeed, the level of the future success of such approaches might be measured by the extent that they entice members of the field of terrorism, since this is not only a large field but one which operates on peculiar sets of incentives. For the moment, it appears that the intellectual movement toward the comprehensive study of violence is gaining ground. If this is the case, however, we believe that a new challenge will emerge. To the extent that an enlarged pool of phenomena covering various forms of violent and nonviolent actions is treated as comparable, the need to arrive at new conceptual distinctions will arise. The challenge ahead might be, then, to produce conceptual differentiation that, while analytically integrating, allows for superior classification of phenomena.

Social Movements, Geography of

Byron Miller, University of Calgary, Calgary, AB, Canada

Abstract

Social movements, like all social phenomena, are geographically constituted. Although social scientists increasingly stress the importance of the context of social action, the geographical constitution of social movements has received comparatively little attention. Increasingly, however, there are exceptions to this generalization. Contemporary approaches to the study of the geography of social movements proceed from the position that the social and the spatial are inseparable, and that social struggle is simultaneously geographical struggle. The resources and barriers that social movements draw upon and encounter – e.g., money, skills, collective identities, social networks, political opportunities, grievances – have their own geographies, giving rise to a geographically differentiated landscape of protest. Likewise, the social relations that social movements attempt to change are geographically specific; change in those relations often necessitates change in the geographic constitution of those relations. Social movements, explicitly or implicitly, must formulate geographically specific tactics and strategies that affect the likelihood of their success or failure.

Social movements, like all social phenomena, are geographically constituted. Although social scientists increasingly stress the importance of the context of social action, the geographical constitution of social movements has received comparatively little attention. However, there are important exceptions to this generalization. For instance, a number of scholars across the social sciences have engaged in projects to map the incidence and spatial diffusion of social movements. Such projects provide compelling evidence of the geographical specificity of the causes of social movement mobilization. These mapping projects, nonetheless, tend to treat the geographies of social movements simply as the outcomes of aspatial mobilization processes or as the 'containers' in which mobilization processes occur.

More contemporary approaches to the study of the geography of social movements proceed from the position that the social and the spatial are inseparable and that social struggle is simultaneously geographical struggle (Soja, 1980; Giddens, 1984). The resources and barriers that social movements draw upon and encounter – e.g., money, skills, collective identities, social networks, political opportunities, grievances – have their own geographies, giving rise to a geographically differentiated landscape of protest. Likewise, the social relations that social movements attempt to change are geographically specific; change in those relations often necessitates change in the geographic constitution of those relations. Social movements, explicitly or implicitly, must formulate geographically specific tactics and strategies that affect the likelihood of their success or failure.

What one means by 'social movements' is open to a wide range of interpretations. For present purposes social movements are defined broadly as collective mobilizations of people seeking social or political change. While social movements necessarily take place somewhere, their geography involves considerably more than an inventory of their locations. Geography is not simply a backcloth onto which aspatial social processes are mapped. Rather, it is a fundamental aspect of the constitution of all social processes, affecting their evolution and outcome directly. It is part of the explanation of social processes, as well as an outcome (Massey and Allen, 1984).

While a variety of geographic concepts can be employed in the analysis of social movements, four core geographic concepts are particularly important: space, place, scale, and networks. Each of these concepts has its own evolution, which can be seen in the ways in which analyses of the geography of social movements have changed over time.

Evolving Geographic Concepts and the Analysis of Social Movements

Spatial Analysis School of Social Movements

The spatial-analytic paradigm that dominated geographical analysis in the 1960s and 1970s worked from a conception of space that was based, by and large, on measures of distance. In this paradigm, social phenomena are described and explained in terms of absolute (e.g., with reference to a fixed grid such as latitude and longitude) or relative (e.g., transportation costs or travel time) location. Virtually all social phenomena have been shown to possess a 'distance decay' function as interaction costs increase with distance from the activity center. The spatial diffusion of information, as well as barriers to such diffusion, became a common theme in much spatial-analytic research, including that addressing social movements (*see* Diffusion: Geographical Aspects). The growth and mobilization of social movements is clearly dependent upon flows of information, as demonstrated by Sharp's (1973) analysis of the spatial diffusion of US postal strikes, and Hedstrom's (1994) work on the spatial diffusion of Swedish trade unions. Most spatial-analytic work on social movements, however, examines the copresence of specific social conditions within clearly delimited places. Adams (1973), for instance, examines the colocation of factors promoting urban protests, while Cutter et al. (1986) consider how characteristics measured at the state level are associated with support for nuclear weapons freeze referenda (*see* Peace Movements, History of). In the 1970s, attempts to explain the occurrence of social phenomena in terms of distance or

colocation came under heavy criticism for ignoring power relations and, in particular, the relation between 'the social' and 'the spatial.'

Contemporary Conceptions of Space and the Analysis of Social Movements

Influenced by the work of Henri Lefebvre and others, contemporary conceptions of space emphasize the mutual constitution of 'the social' and 'the spatial.' Space is seen increasingly as a necessary component of the constitution of power relations. Equally significant, space is no longer conceptualized primarily in terms of the physical location of material objects. Instead, both material spatial practices, as well as symbolic or representational spaces, are examined.

As political economy approaches swept through the social sciences in the 1970s and 1980s the geography of social movements was explicitly linked to the spatial constitution of material interests. The relationship between the geography of political and economic conditions and the incidence of protest is demonstrated in detail in Charlesworth's (1983) atlas of rural protest in the UK. Bennett and Earle (1983) show that the failure of socialism in the United States can be linked directly to geographic patterns of wage and skill differentiation; where differentiation was substantial, working class solidarity was undermined (*see* Labor Movements, History of). Similarly, Massey (1984) argues that the spatial division of labor directly shapes the material interests that underlie political movements. Markusen (1989) makes a somewhat different point: a region's stage in the profit cycle shapes the types of movements that are likely to emerge in it. Environmental movements are more likely to emerge in economically booming regions where rapid growth places stress on the environment, while progrowth politics are common in regions of decline (*see* Social Movements: Environmental Movements).

Geographically differentiated state systems also shape the geography of social movements. Kitschelt's (1986) comparison of the political structures of France, Sweden, West Germany, and the United States shows that differences in central state structures are related to national-level variations in antinuclear mobilization. Other studies link local-level variation in social movement mobilization and success to differences in political opportunity structures among local states (Duncan et al., 1988; McAdam, 1996; Tarrow, 1996). In the United States, many social movements began as highly localized movements in politically opportune places, then spread nationally (*see* Citizen Participation).

Symbolic or representational spaces affect the geography of social movements as well. The symbolic codings of spaces, i.e., the often subtle and unacknowledged signs that shape people's reactions to spaces, may indicate belonging for some groups and exclusion for others, empowerment for some groups and repression for others, safety for some groups and danger for others. Such codings can foster or hinder social movement mobilization. The creation of symbolic space is intertwined with the process of collective identity formation, as Marston (1988) shows for ethnic identity, Rose (1993) demonstrates for gendered identity, and Ruddick (1996) illustrates for interlocking 'race,' class, and gender identities (*see* Social Movements and Gender). Such identities are crucial to the formation of solidarity necessary for movement mobilization (*see* Social Movements, History of: General). The dominant symbolic codings of space are open to contestation, and counter-representations are often constructed by insurgent groups (Cresswell, 1996). Representational spaces, and their internalization, relate directly to the ways in which social movement messages resonate in some places, and not in others.

Place and the Analysis of Social Movements

Many geographic analyses emphasize the place-based constitution of social processes. Place is best understood as a multidimensional concept entailing 'locale,' i.e., the geographical setting of everyday social relations, 'location,' i.e., geographical position vis-à-vis wider scale interactions; and 'sense of place,' i.e., the esthetic and emotional bonds to locale (Agnew, 1987). The concept of place stresses the unique ways in which social processes may interact in specific milieus, calling our attention to the 'situatedness' of all human action and institutions. At the same time, place is not to be equated with 'the local.' Place implies the articulation of localized processes, with other processes operating at broader scales.

Much of the geographical literature on social movements stresses the ways in which identities and allegiances are shaped in place. Thrift and Williams (1987) analyze the ways in which consciousness and identity are produced through place-specific social practices and the time–space paths of individuals' everyday lives. Katznelson's (1981) work can be interpreted as a place-sensitive analysis of US workplace and community politics, stressing how distinct places shape identity in distinct ways. Savage's (1987) analysis of British working-class politics demonstrates how the interactions of workplace and lifeworld spaces have effects on identity that vary from place to place. Recent work on identity construction stresses the place-specific interplay of spaces of production, reproduction, and the state that produce multiple, fragmented, and sometimes contradictory identities, all with direct implications for social movement mobilization (Ruddick, 1996; Cope, 1996; Brown, 1997). Place itself can be a primary basis for collective identity construction. The defense of places associated with specific collective identities is a common theme of many new social movements (Melucci, 1994; Martin, 2003). Increasingly, cities find themselves in competition with each other for capital investment; in response, place-based identification and coalition building has often taken precedence over class and other axes of social identity (Hudson and Sadler, 1986; Swyndegouw, 1989).

Identity is not all that is shaped in place. Agnew (1987: 59) observes that "different places produce different degrees and orientations of organizational capacity." Routledge (1993), for example, shows that social and environmental movements in India faced opportunities for, and constraints to, mobilization that relate to place-specific social networks, systems of meaning, and patterns of political repression. Miller (2000) shows how a variety of place-specific characteristics, including political opportunity structures, available resources, material interests, and attachments to place, shaped the strategies and effectiveness of peace-organizing differentially in several Boston area municipalities.

Scale and the Analysis of Social Movements

The concept of place clearly carries within it issues of geographic scale. Geographic scale has commonly been thought of as a fairly straightforward technical issue relating to the telescoping frame of geographic analysis (from local to global), but such a notion of scale as pregiven or unproblematic is strongly challenged, especially in political geography. While many analyses of social movements may assume that the appropriate scale of analysis is the nation-state, such an assumption overlooks the often critical subnational, as well as international, constitution of social movement processes. Moreover, rather than being seen as an 'external fact awaiting discovery,' scale should be viewed as a "way of framing [and acting on] conceptions of reality" (Delaney and Leitner, 1997: 94–95) that is employed by social movement organizations and their opponents as a way of gaining political advantage. As Smith (1993: 90) explains:

> The construction of scale is not simply a spatial solidification of contested social forces and processes; the corollary also holds. Scale is an active progenitor of specific social processes. In a literal as much as metaphorical way, scale both contains social activity and at the same time provides an already partitioned geography within which social activity takes place. Scale demarcates the sites of social contest, the object as well as the resolution of contest.

Tarrow and McAdam (2005) point to two mechanisms by which social movements shift geographical scales: 'relational diffusion' addresses the territorial broadening of social movements through preexisting social networks, while 'brokerage' refers to the building of new network connections beyond the initial geographical territory of a struggle. While Tarrow and McAdam focus on 'horizontal' scalar relations of social movement agents, other analyses of scale focus on 'vertical' state relations by which the capacities and responsibilities of local, regional, national, and transnational institutions of the state are constituted, challenged, and altered (Brenner, 2004), in turn altering the capacities – and relevance – of the state institutions that social movements engage. Social movements adopt scale-specific strategies in response to the presence of political opportunities, as well as potential allies, at different scales of the state (Cox, 1997; Miller, 2000; Tarrow and McAdam, 2005; Nicholls et al., 2013).

Networks and the Analysis of Social Movements

Since the early 2000s much of the geographic research on social movements has focused on the formation of social movement networks. The principal theoretical foundation for much of this research has been Bruno Latour's actor-network theory (ANT), which focuses on "uncovering and tracing the many connections and relations among a variety of actors (human, nonhuman, material, discursive) that allow particular actors, events and processes to become what they are" (Bosco, 2006: 136). ANT differs considerably from the predominantly structural sociological approach to actor-networks. Instead of mapping the structure of network connections, ANT takes a poststructural approach to understanding the fleeting associations of heterogeneous human actors and nonhuman actants, attempting to break down the boundaries between the human and nonhuman worlds, and between structure and agency. Dissolving boundaries and tracing the formation of relationships is at the heart of this topological approach to network formation, an approach typically considered as 'relational' and counterposed to territorial notions of place and space. ANT approaches blossomed with the rise of antiglobalization movements that involving transnational organizing and, indeed, ANT-inspired approaches have yielded important insights into how antiglobalization movements organize and build identities and solidarities across national borders. Routledge (2003), Featherstone (2008), and Routledge et al. (2013) show how shared identities and solidarities are dynamically constructed and reinforced through transnational mobilization processes and that geographical notions of identity formation must consider the extralocal networks that are critical components of place-based social relations. Nonetheless, networks do not stand outside constructions of territory, scale, and place, which are themselves relationally constructed.

Despite the substantial insights yielded by each of the geographically oriented bodies of social movements research, there has been considerable debate over the ostensible superiority of one approach or another. But as Nicholls (2009: 78) argues,

> What has been interesting about these debates is not that one position is more persuasive than the other but that these various positions have contributed to revealing the mechanisms and dynamics associated with the various spatialities of human relations. The central analytical task at hand is therefore not to show how one form of spatiality is more important than another, but rather to show how these spatialities articulate with one another in actually existing social movements.

Geographic Tactics and Strategies of Social Movements

Given that all social movements are geographically constituted, all social movement organizations must make decisions regarding the geographic tactics and strategies they employ. Sometimes these decisions are explicitly considered, often they are not.

Social movements frame their messages in particular ways that they hope will resonate with particular groups (Martin, 2003). Given highly differentiated geographies of culture, symbolization, and interests, the resonance of any given frame will depend in substantial measure on the geographic targeting of the message. Similarly, the recruitment of social movement members is inextricably intertwined with the geography of mobilization activities (Harvey, 1985; Miller, 2000; Nicholls et al., 2013).

While identities constructed in place and place-based identities frequently are central to social movement solidarity, the absence of such bases of solidarity can be rectified through efforts to construct new places of group interaction and identity. Castells (1983), for example, details how the growth of gay bars, businesses, and gathering places was crucial to the construction of shared identity in the San Francisco gay

community. Castells also illustrates how, in the case of the Madrid citizens' movement, the construction of a community center in the Orcasitas shantytown was essential to breaking down social walls and building broad, place-based bonds around which the movement organized. Moyersoen and Swyngedouw (2013), going a step further, show how the creation of an innovative community center can actually serve to 'broker scales,' opening up entirely new opportunities for the creation of broader scale social interactions, negotiation, and bonding. Indeed, places – and especially cities – can be thought of as 'relational incubators' through which both strong and weak bonds are formed even as the processes that shape these places stretch around the globe (Miller and Nicholls, 2013).

The tactics and strategies that social movements employ to challenge the existing social order are rooted in an often-unexamined normative geography. Cresswell (1996) makes a compelling case that spatial structures and systems of places provide ideologically loaded schemes of perception. Dominant conceptions of what is 'normal' and 'appropriate' is defined "to a significant degree, geographically, and deviance from this normality is also shot through with geographic assumptions concerning what and who belong where" (p. 27). He illustrates his argument with several examples, including that of the Greenham Common women's peace camp that challenged British participation in the nuclear arms race through 'out of place' behavior that "denaturalized the dominant order [and] showed people that what seemed natural, could, in fact, be otherwise" (p. 125). Similar challenges to the authority of the state and of finance capital occurred, respectively, through the occupation of public squares across North Africa during the Arab Spring and of Zuccotti Park during the Occupy Movement.

Indeed, social movements can be mobilized and social conditions can be changed through a resymbolization of existing spaces or through a reterritorialization of existing symbolization (Pile and Keith, 1997). Harvey (1989: 233) makes a case for the resymbolization of space when he argues:

> If workers can be persuaded … that space is an open field of play for capital but a closed terrain for themselves, then a crucial advantage accrues to the capitalists … power in the realms of representation may end up being as important as power over the materiality of spatial organization itself.

An example of the reterritorialization of existing symbolization can be found in the work that has been done in several US metropolitan areas to recast the ongoing political battles between central cities and suburbs. In several metropolitan areas, this common conception of territorial interests is being replaced with one that aligns the central cities with the inner ring suburbs, creating a far more powerful territorial alliance behind the movement for a more equitable metropolitan distribution of affordable housing, school funding, and tax revenue (Orfield, 1997).

Many of the efforts of social movements to redefine the spaces of struggle involve attempts to 'jump' to a more favorable geographic scale (Smith, 1993). In addition to changing symbolic geography, altering the scale of material processes can be central to social movement strategy. Examples include shifting from regional to national-scale labor bargaining (Herod, 1998), and seeking out more favorable political opportunity structures at a different level of the state, e.g., local rather than central (Miller, 2000; Nicholls et al., 2013).

The geographic tactics and strategies adopted by social movements and their opponents play a powerful role in the nature of social movement mobilization and the degree of success or failure social movements achieve.

Abstract

The chief focus of this article is the history of social movements in the West that have attracted most scholarly attention; it draws particularly on studies done in the years 1975–2000 – a period in which the concept of social movement has been redefined and developed – for its theoretical framework and empirical base. The British movement for the abolition of slavery – an emblematic, and by some criteria the first social movement – serves as a concrete example of an early crusade that embodied many of the central features of the phenomenon. The article goes on to examine the movement for women's suffrage in the United States, Italian fascism, and transnational social movements such as proecology/environment organizations.

Social movements, according to sociologist Sidney Tarrow's definition, are "collective challenges, based on common purposes and social solidarities in sustained interaction with elites, opponents and authorities" (Tarrow, 1998: p. 4). This definition, derived from studies of both historical and contemporary social movements, locates the earliest movements in the late eighteenth and early nineteenth centuries. The emergence of social movements was contemporaneous with (1) the increased centralization of national states that accompanied war and revolution in Western Europe and North America; (2) the rise of the popular press and the circulation of notions of natural rights and liberty put forward by Enlightenment and revolutionary thinkers; and (3) particularly in England and the English-speaking colonies of North America, the rise of evangelical and nonconforming religions in which literacy and reading were cultivated and principles of human rights formulated. From that period and place, social movements have proliferated to the world.

The chief focus of this article is the history of social movements in the West that have attracted most scholarly attention; it draws particularly on studies done in the years 1975–2000 – a period in which the concept of social movement has been redefined and developed – for its theoretical framework and empirical base. The British movement for the abolition of slavery – an emblematic, and by some criteria the first social movement – serves as a concrete example of an early crusade that embodied many of the central features of the phenomenon.

The Abolition of Slavery in Great Britain

The eighteenth- and nineteenth-century British abolitionist movement was distinctive in that it was aimed at an institution that had only a minor presence in Great Britain, whereas most social movements have been concerned with issues close to hand. Slavery nevertheless involved many Britons; British ships sailing from Liverpool were active in the slave trade carrying slaves to Africa and slaves to the Americas, and the 'peculiar institution' was common in Britain's North American and universal in its Caribbean colonies. The question of the legality of slavery in Britain was raised as early as the 1720s, but it was not until 1772 that Lord Chief Justice Mansfield ruled that slavery was illegal under English law. English members of the Society of Friends had developed the earliest critique of slavery as contrary to Christian teaching, and local Quaker meetings first excluded slave traders in 1761 and later slave owners from membership.

Quakers then turned to political action to end British involvement in the slave trade, establishing in 1787 the Society for the Abolition of the Slave Trade, commonly known as the London Committee. This organization welcomed non-Friends as members, and recruited both middle- and working-class adherents. The political technique utilized by the Committee in this and later campaigns was mass petitions to Parliament. Thomas Clarkson, a gifted organizer, and other activists worked outward from London and local Friends meetings to form regional organizations, recruit members, distribute leaflets, and collect signatures on petitions to Parliament calling for the end of the slave trade. (Clarkson and his associates began their crusade with an exclusive focus on the slave trade, as less contentious than abolition.) Visual images portraying the horrors of the slave trade such as a print of the cross section of a slave ship with its tightly packed human cargo and Josiah Wedgwood's medallion of a kneeling chained slave, inscribed with the motto "Am I not a Man and Brother?" were highly effective in attracting supporters.

There was an outpouring of support, with about 60 000 male signers on the first petitions, including 11 000 men from Manchester, the center of the burgeoning cotton spinning industry. Parliamentary sympathy for the cause seemed strong up to 1792, when 519 petitions with up to 400 000 signers were collected. However, legislative support dropped with the slave revolt in Haiti, the contemporaneous radicalization of the French Revolution, and the outbreak of war against France. In 1794, the House of Lords decisively rejected the abolitionist resolutions presented to it.

Political opportunities for action on abolition reappeared in 1804, after Britain's victories in the Napoleonic Wars and its seizure of the French Caribbean colonies. Clarkson and other organizers again canvassed the country seeking signatures; he

also sought support from members of Parliament, in particular William Wilberforce, an Evangelical MP from Yorkshire who spoke eloquently about the evils of the trade and Samuel Whitbread, a nonconformist Protestant already known as a social reformer. Clarkson's powers of persuasion and his Parliamentary allies combined to produce in 1807 a majority vote in Parliament to forbid British ships' participation in the slave trade to both British possessions and foreign slave-holding colonies. The African Institution, founded in the same year, took as its task ascertaining the effectiveness of the British legislation.

Although British diplomats signed agreements eschewing the slave trade with other European powers, and indeed paid compensation when they did, the results were uneven. British activists resolved to continue their efforts, founding the Society for the Amelioration and Gradual Abolition of Slavery (known familiarly as the Anti-Slavery Society) in 1823 and the Agency Committee (1831), which demanded immediate and unconditional slave emancipation. The Agency's professional organizers traveled around England, promoting local petition drives and pressure on candidates in the Parliamentary elections to declare their support of full abolition. Members of the House of Commons elected under the 1832 Reform Act were ready to vote for the abolition of slavery in British possessions, but the House of Lords was not. The outcome was a compromise Emancipation Act of 1833 that set 1 August 1834, as the date on which slavery would end, but stipulated a complex gradual process to complete freedom.

The former slaves would become 'apprentices,' working for pay three-quarters of their time for their ex-masters; one-quarter of the ex-slaves' time was to be reserved for them to cultivate their newly granted plots. Slave owners would be compensated by the state for the loss of their 'property.' The story did not end there, however. Disagreements about strategy between the Anti-Slavery Society (which had accepted the compromise Emancipation Act) and the Agency (which had not) continued, and the latter established yet another organization (the Central Negro Emancipation Committee) and sought to persuade Parliament that oppressive conditions still prevailed. In the end, the complex system based on the 1833 Act proved difficult to manage, and the planters themselves ended apprenticeship in 1838.

The international abolition movement matured in the 1830s, and began to hold annual congresses (which some American abolitionists attended) in 1840. The United States Civil War (1861–65) was the outcome of a series of legal and political disputes about slavery and state's rights. In 1863, President Abraham Lincoln's Emancipation Proclamation ended slavery in the Confederacy, and during the postwar Reconstruction the Thirteenth, Fourteenth, and Fifteenth Constitutional amendments (which completed abolition, made the ex-slaves citizens, and guaranteed their right to vote) were ratified. The abolition of slavery in Cuba (1886) and Brazil (1888) ended legal slavery in the West.

The Social Character of Movements

Over the period 1975–2000, sociologists have begun to define 'contentious politics' – confrontations of ordinary people with authorities and/or elites – as the building blocks of social movements. Sidney Tarrow defines the conditions under which contentious politics is triggered:

> When changing political opportunities and constraints create incentives for social actors who lack resources on their own, they contend through known repertoires of contention and expand them by creating innovations at their margins. When backed by dense social networks and galvanized by culturally resonant, action-oriented symbols, contentious politics leads to sustained interaction with opponents. The result is the social movement.
>
> Tarrow, 1998: p. 2

The case of the British movement for the abolition of the slave trade and slavery illustrates this definition:

1. the movement was collective and interactive, between authorities and the populace; it was conducted early on through organizations established for the purpose and spread by movement professionals;
2. it was aimed at political authorities (in this case Parliament) that could take action to achieve the movement's goal;
3. each phase of activism on abolition began with an opening of political opportunity and ended when new political constraints closed off forward movement;
4. the network of Quaker meetings was the first activated in the cause, but other church groups and local branches of the antislavery societies joined the abolitionist network over the period;
5. interaction was contentious and drew on symbols that helped promote action; and
6. participation in the movement came to be perceived by activists as constitutive of their identities.

Woman's Suffrage in the United States

The formation of the United States woman's suffrage movement was closely connected to the social groups and organizations that promoted the abolition of slavery there. For example, American woman's suffrage activists Lucretia Mott and Elizabeth Cady Stanton first met each other at the London World Anti-Slavery Convention of 1840, where they discussed the possibility of forming an organization to promote women's rights. Mott, a New Englander then living in Philadelphia and the senior of the two, had founded the first Female Anti-Slavery Society in the United States; her home was a stop on the 'underground railroad' through which slaves escaped to Canada and freedom. The well-educated daughter of a judge, Stanton was born in western New York State, married an abolitionist leader, and eventually settled with her family in Seneca Falls, New York. Stanton and Mott renewed their acquaintance in 1848, when they and three like-minded women issued a call to a women's rights conference in the summer. To their surprise, some 300 women and men came, applauded Stanton's speech echoing the Declaration of Independence and passed a resolution on women's suffrage: "Resolved, that it is the duty of the women of this country to secure to themselves their sacred right to the elective franchise."

The movement developed slowly through annual conferences, spreading primarily to the Middle West and East coast. In 1851, Stanton met Susan B. Anthony, then a paid organizer in the temperance movement. Anthony brought her organizational skills to women's rights, beginning a drive in 1854 based on organizers in each county of the state of New York who recruited local women. These in turn collected signatures for a petition calling for women's control of their own earnings, mothers' guardianship of children in divorce, and women's suffrage. The first concrete accomplishment – a New York state law granting women property rights – was passed in 1860.

With the outbreak of the Civil War in April 1861, organizing efforts were temporarily suspended. Not for long, however, as Anthony and Stanton reactivated their abolitionist and women's rights networks in 1863, issuing a call to a mobilization meeting in New York. The outcome was the National Women's Loyal League that set to work gathering close to 400 000 signatures on a petition for the Thirteenth constitutional amendment that would free the slaves. Women also served on the Civil War Sanitary Commission, which raised funds and organized and administered nursing and support services for the military hospitals and convalescent centers.

The campaign for ratification of the Fourteenth and Fifteenth amendments (the first made male ex-slaves citizens and the second granted them the vote) split the former abolitionist movement colleagues between those who supported rights for the ex-slaves as a first priority, and those who supported universal suffrage. In 1869, two new organizations dedicated to women's suffrage emerged from the split: the National Woman Suffrage Association founded by Anthony and Stanton, which objected to the Fourteenth and Fifteenth Amendments because they specified male ex-slaves; and the American Woman Suffrage Association, founded by Lucy Stone, her husband Henry B. Blackwell, and Mary Livermore. These associations pursued the cause by different methods and separately for 20 years during which the westward movement was completed, the country industrialized, and new women's associations such as the Women's Christian Temperance Union (1874) and the National Association of Colored Women (1895) were founded. In 1890, the National and the American Associations merged to form the National American Woman Suffrage Association, with Elizabeth Cady Stanton as its first president; she was succeeded 2 years later by Susan B. Anthony who served to 1900.

Led after 1900 by Carrie Chapman Catt, a gifted organizer, the National American Association continued its strategy: seeking constitutional change state by state. Catt resigned in 1904 to play an active role in founding the International Woman Suffrage Alliance launched that year. There was little activity around the woman suffrage ('Susan B. Anthony') amendment to the United States Constitution for over 10 years. New tactics appeared in 1913, devised by the more militant new movement recruits Alice Paul and Lucy Burns who were appointed to the National American Suffrage Association's Congressional Committee. They promptly organized a demonstration of some 5000 women who marched in Washington in support of a constitutional amendment the day before Woodrow Wilson's inauguration for a second term. Despite the organization's permit for the parade, the police were unprepared for the crowd reaction and the women were mobbed and jeered. Later that year, Paul and Burns established the Congressional Union, and their organization eventually became independent of the National American, which continued to pursue its state-by-state strategy, with only slow progress.

In 1915, Carrie Chapman Catt agreed to lead the campaign for women's suffrage in New York State, and once again became president of the National American Suffrage Association with a newly energetic board committed to her plan for a renewed campaign for a national constitutional amendment. (The Congressional Union and its successor the Woman's Party did not join the effort. The Woman's Party nevertheless contributed to the process by courting arrest through disruptive and provocative action, which made the National American's actions look reasonable.) At its convention in late 1917, the latter warned that if Congress did not approve the suffrage amendment before the next election, it would adopt the British suffragette method: opposing the election of Congressional candidates who opposed the federal amendment, no matter what their party. The amendment passed in the House of Representatives by the required two-thirds majority in January 1918, the Senate in 1919, and ratification by the requisite proportion of states was completed in 1920.

Twentieth-Century Social Movements: Italian Fascism

In the early twentieth century, several movements demonstrated unequivocally the adaptability of the social movement to regressive ends. The Italian Fascist movement serves as an example.

After the end of World War One late in 1918, Italy was swept by waves of contentious politics: demobilized troops demanded jobs; peasants and agricultural laborers agitated for land; consumers called for price controls; and workers struck for higher wages. Among the groups engaging in collective action were the *fasci di combattimento* founded by Benito Mussolini (formerly a revolutionary socialist) who convened the first *fascio* in Milan on 21 March 1919. At a public rally 2 days later, the national program was only vaguely described (it was not fully formulated and publicized until months later). The program called for integration of all Italian 'national' territory into the nation, and pledged to oppose all neutralist politics no matter the party involved; other radical social and political demands included universal (male) suffrage, a constituent assembly, a republic with local autonomy, the 8-h day, worker participation in factory management, land to the peasants, elimination of the Senate and all noble titles, and an end to conscription, expropriative taxes, speculation, and monopoly.

The Fascists' first public action (15 April 1919) was a counterdemonstration together with students, World War veterans, and revolutionary syndicalists, which attacked an anarchist/socialist march protesting repression in Milan. It ended with the sacking and burning of the headquarters of the socialist newspaper *Avanti*! In the next 2 years, most Italian popular contention was dominated by socialists and organized social Catholics (represented by the newly founded Popular Party) who both sought to control and lead the strikes in northern industries and large-scale agriculture in the Po Valley, the land occupations, and eventually in fall, 1920, the factory occupations. These struggles all occurred in northern Italy,

where socialist and Popolari strength was concentrated. The Fascist counterattack from its urban bases (again in the north) began in the same period: physically assaulting unionized farm workers on strike, the headquarters of peasant leagues, cooperatives, and unions, burning left wing newspapers' offices and printing plants, and breaking up meetings of the socialist communal councils as well.

Socialist and Popular Party organizations crumbled as Fascist membership and attacks both increased. The Fascists had become a political force to be reckoned with and their success went hand in hand with the demobilization of the left. In August 1921, Mussolini signed the so-called Pacification Pact with the socialists and Popolari, promising to eschew violence, but his followers forced him to back away from the agreement and he publicly renounced it later in the year. He also announced the formation of a political party, which he described as a rival to the state, outside traditional politics. Violent clashes between socialists and Fascists continued into 1922, when the Fascist threat to seize the state forced the cancellation of a general strike planned by an ad hoc group of unions; by then the entire Po Valley, and much of North and Central Italy was in Fascist hands.

As the constitutional parties called for a new government, Mussolini threatened to march on Rome to seize power. The march never happened; instead, Fascist Black Shirts occupied provincial government and party headquarters, post offices, and police stations (again in the north, where socialist power had been concentrated) sometimes without resistance. Fascist threats and his own concerns led the king to refuse to sign the declaration of martial law that the prime minister had drawn up, and Mussolini's first government (based on a coalition of center and right parties) was formally constituted on 31 October 1922. Mussolini used nationalism wreathed in patriotism as a weapon against the left, and he continued to be a master of language and image once in power.

Although there had been social movements in the European colonies (and in China, as well) before the outbreak of World War I in 1914, there were many more non-Western movements in the twentieth century; they ranged in principal concerns from nationalism to widow burning and female circumcision (in India and Kenya, respectively). Nationalists sometimes rejected Western notions of modernity and connected customs that seemed unacceptable to Westerners to colonial cultural authenticity. Two examples are Mahatma Gandhi in his representation of himself with a spinning wheel and in his advocacy of *khadi* (handspun and woven cotton cloth, which he himself wore in his later years), and Kenyan nationalist Jomo Kenyatta who defended female circumcision on behalf of the Kikuyu Central Association, a preindependence nationalist organization. More recently, televised news reports and rapid communication by telephone, fax, and e-mail have made possible the almost instantaneous transmission of news not only in print, but of visual images as well. To what extent can we speak of transnational social movements?

Transnational Social Movements

The above discussion of antislavery and women's rights as social movements notes the international dimensions that were integral to social movements even in the late eighteenth century; similarities and connections of social movements across borders are not new. Sidney Tarrow offers a more restrictive definition of a transnational social movement:

> sustained contentious interactions with opponents—national or nonnational—by connected networks of challengers organized across national boundaries … What is important … is that the challengers themselves be both rooted in domestic social networks and connected to one another more than episodically through common ways of seeing the world, or through informal or organizational ties, and that their challenges be contentious in deed as well as in word.
>
> 1998: p. 184

Tarrow discusses three movements that fit his definition: the contemporary ecological and environmental movement, the European and American peace movement of the 1980s, and Islamic fundamentalism.

The ecological/environmental movement, which mounted coordinated worldwide Earth Day demonstrations in the late 1970s and early 1980s, provides the example discussed here. Some of its social movement organizations and their coordinated activities across borders do qualify as transnational organizations, as Tarrow demonstrates. Greenpeace, for example, has been a genuinely transnational social movement organization, with professional organizers and offices in many countries, and supporters who share a common world view and are willing to support its advocacy. Founded in Vancouver, Canada, according to its 1992–93 report it had over 5 million supporters (contributors), 43 offices, and over a thousand paid employees. It developed out of domestic movements that had similar goals, organized advocacy networks, and conducted contentious politics that cross national boundaries. Its members and sympathizers demonstrated against French nuclear testing in the Pacific and against abusive fishing for whales by Japanese and Soviet whalers.

Nevertheless, most international connections are less sustained and less professionalized than Greenpeace. Not all issues can attract support across the varied conditions of world polities, and most political, social, and economic international movements continue to work within states and national-level private institutions like large business organizations or labor unions rather than through transnational voluntary associations that represent individuals' world views directly.

Overview: Social Movements from the Eighteenth to the Twentieth Century

Sidney Tarrow's definition of the social movement (quoted in the opening sentence of this article) posits its applicability to the entire period since the first appearance of social movements in the late eighteenth century up to the present. His definition is based on the premise that, although the issues and tactics of social movements have changed over the two centuries in which they have proliferated, the defining form of social movements – their collective nature, common purposes, and shared base in social solidarities with roots in the social

structure in which they occur – have remained relatively unchanged. Not all social movement scholars agree with this premise; among European sociologists and political scientists in particular the concept of 'new social movements' has been developed since 1985.

Kriesi et al. (1995) argue that a new type of social movements, which address similar issues yet vary significantly in form according to the national political context, has emerged in Western Europe since 1968. Kriesi and his colleagues emphasize contemporary cross-national variation in domestic politics and corresponding differences in the timing and other characteristics of social movements. The examples that they discuss under the rubric of new social movements include "the ecology movement (with its antinuclear energy branch), the solidarity movement (with the Third World), the contemporary women's movement, the squatters" movement, as well as various other movements mobilizing for the rights of discriminated-against minorities' such as gays (1995, p. xii). The new type of social movements discussed by Kriesi et al. (1995) is classified according to the chief constituencies of the movements and the connections among them. Tarrow's definition of social movements leaves open the characteristics of their members and their goals and stresses the movements' long-standing form. Two alternatives present themselves: in terms of their political concerns and context then, recent social movements may herald changes in some aspects of movement politics and require redefinition of the concept. Alternatively, the broad definition with which this article begins argues for stability in the form of social movements even as the issues that bring them into the public arena change. Whether one of these alternatives will contribute to understand contemporary and future social movements better is an empirical question that can only be determined with a longer span of observations.

Social Movements: A Social Psychological Perspective

John Drury, School of Psychology, University of Sussex, Falmer, Brighton, UK

Abstract

This article analyses the treatment of social psychological issues in the study of social movements. It traces historically the development of theory in the study of social movements, from accounts of 'societal breakdown' and 'collective behavior,' through resource mobilization theory, and the 'new social movements' approach. More recent 'social constructionist' approaches to social movements will be outlined, which explicitly foreground the topic of identity and its creation. Finally, there is a discussion of the concept of 'interaction' in social movement theories, which in different forms has been understood as the process whereby new identities are created in social movement activity.

Introduction

Social movements have been defined as collective challenges by people who have a shared aim and solidarity, who act in a sustained way against opponents, particularly those in power (Tarrow, 1998: p. 9). While much research on the activity of social movements – i.e., collective action – takes place within social psychology, the study of social movements is dominated today by sociology and political science. Yet social psychology has always provided perspectives on the topic of social movements. And many sociological theories of social movements make psychological claims or use psychological concepts. Indeed, by their nature, social movements raise many social psychological questions. Thus, one point that many of those who study social movements today agree on is that, as well as potentially contributing to material social change, social movement activity can create *identities* for social movement actors. However, social movement theories have not always acknowledged this creativity. Indeed, for many years, social movements were conceptualized such that the question of identity creation could not arise.

This article will trace historically the development of theories of social movements, beginning with the earliest accounts of 'societal breakdown' and 'collective behavior,' and focusing on the social psychological question of identity construction. The article will show how later dominant perspectives – in particular resource mobilization (RM) theory and the 'new social movements' (NSMs) approach – in different ways each pointed to the necessity of a concept of identity and hence raised social psychological questions. In the second half of the article, more recent 'social constructionist' approaches to social movements will be outlined, which explicitly foreground the matter of identity and its construction.

A number of social movement theories, from different perspectives, highlight the role of *interaction* in the identity construction process. However, from a social psychological perspective, this concept is not always fully explicated. In particular, research on *social identity* suggests that the concept of 'interaction' can refer to a range of different types of process, and that these different processes might themselves 'interact' in important ways within social movement activity. The final sections of the article discuss concepts of interaction in social movement theories and social psychology.

The Occlusion of Rationality in Social Movement Theory: 'Societal Breakdown' and 'Collective Behavior'

Theories of social movements find their origins in the late nineteenth and early twentieth centuries in the work of such names as Tarde, Le Bon, Marx, Weber, and Durkheim. This was a period of revolutionary upheaval across Europe, and social and psychological theorists were often concerned with issues of immense social significance. Thus, Marx was interested in the practical question of whether particular working class movements were capable of overthrowing capitalism; Marx hoped they would. As a sociologist, Weber was interested in this kind of question too, but from the opposite side of the barricades, as it were. Weber tended to view crowds and masses with trepidation; they were seen as aspects of transition, perhaps necessary, but temporary, he hoped. Weber's (1978/1922: pp. 241–245) studies of charismatic leadership link it with irrationality and therefore point more to the dangers of collective behavior rather than to any positive potential; Weber preferred the 'mature' politics of the organized trade unions to the 'mass' politics of social movements (Eyerman and Jamison, 1991: p. 15).

At this time, theories of crowd behavior emerged that focused almost entirely on these supposedly inherent dangers of collective activity. These theories were developed to explain the phenomenon of the (proletarian) crowd in order to combat it and to justify effective methods of suppression (*see* Collective Behavior, Social Psychology of, this volume). However, of the many European bourgeois intellectuals proposing theories of the crowd during this period, only one has retained a place within modern social psychology – Gustave Le Bon. Le Bon (1947/1895) provided a popular synthesis of the ideas of many of the other crowd theorists of the time, according to which the 'primitive' psychology of the crowd to some extent generalized to all collective forms. This assumption influenced subsequent accounts of collective behavior for decades to come. As a consequence, early accounts of social movements tended to reproduce the notion that social movement activity was linked to irrationality.

In the twentieth century, the approaches of Herbert Blumer and Talcott Parsons informed a perspective on social movements that dominated the field at least until the late 1960s. Their approaches shared two assumptions: that individuals

behaved differently in groups and that individual deprivations, breakdowns of the social order, and homogenizing ideologies were important preconditions for the emergence of social movements (Mayer, 1991). The basic Parsonian model of social movement emergence was that of a breakdown in norms due to failures in the organs of the social system responsible for social control or social integration, which led to 'strains' and thence to collective behavior (e.g., Parsons, 1969: pp. 85, 110). In the Blumer account (e.g., 1951), which criticized yet was clearly influenced by that of Le Bon, collective behavior was said to follow a life cycle of stages, starting with structureless crowds and ending with the formation of institutionalized social movements. Movements were said to emerge through simple processes of rumor, contagion, and imitation. Blumer also pointed to some positive aspects of collective behavior, however, such as the potential social creativity that might accompany the breaking of the routines of normal, institutionalized behavior.

The most elaborated Parsonian structural–functional 'strain' theory of social movements is that of Smelser (1962). Smelser's 'master proposition' is that "[p]eople under strain mobilize to reconstitute the social order in the name of a generalized belief" (Smelser, 1962: p. 385). Smelser's model identifies various kinds of generalized belief (e.g., hysteria, wish fulfillment, hostility, etc.), and the conditions (such as panic) under which people develop and act on such beliefs. In Smelser's 'value-added' structural model, determinants of collective behavior at a higher level of the explanatory hierarchy (e.g., structural conduciveness and strain) act as preconditions for determinants at the next stage. Like all theories assuming that society is essentially a functional system, what was of interest to Smelser about social movements was first, the types of strains within the system that would give rise to such movements; second, the way such movements become co-opted back into the conventional order (this was Smelser's measure of their 'success'); and third, the way movements develop from an 'undirected' to a 'directed' (organized, coherent) stage (Banks, 1972).

Followers of Blumer developed symbolic interactionist accounts of collective behavior. Within this perspective, Turner and Killian's emergent norm theory (Turner and Killian, 1957) has been influential. It departs from the tenets of the Le Bonian tradition in two important respects. First, it claims that collective behavior is structured by norms – i.e., shared definitions of right and wrong that supply justification and coordinate action between people in particular situations. Second, it argues that the uniformity observed in crowd behavior does not emerge quickly through simple 'contagion' processes but rather develops only gradually. Collective behavior is said to emerge from a background within which norms derived from tradition and institutionalization are not available. Since the established social organization ceases to provide direction, crowd members seek new norms in order to define the situation and act within it. The norms that come to shape collective behavior are developed by crowd members themselves, through interaction and hence symbolic exchange (*see* Collective Behavior, Social Psychology of, this volume).

Despite differences in emphasis, the various types of models prevalent during this period all assumed that social movements did not have the capacity to influence societal development or policy outcomes (Mayer, 1991). In functionalist sociology, collectivities in conflict with 'dominant value systems' were categorized as 'deviant.' Being pathologized in this way, social movements by definition could not be *creative* of anything, whether of new improved forms of society or of themselves in meaningful ways. Hence an analytic division was established between social movements and social change (Banks, 1972). Although Turner and Killian (1957) recognized and attempted to theorize the ability of collectives to create norms, they were still committed to the assumption of the 'collective behavior' tradition that there are 'lower' (normless, irrational) forms of collective phenomena (such as riots, lynchings, panics, and crazes) that could develop into 'higher' ones, which have norms (such as social movements). Again, only collectivities that were seen as having become integrated as part of conventional modes of life – such as the modern trade union movement – were studied outside this broad 'pathology' paradigm.

The Turn to Rationalism in Social Movement Theory

In the 1960s, 'new' movements, such as the civil rights campaigns, anti-Vietnam protests, and the countercultural hippy movement all forced social movement theorists to face issues of power, conflict, and change. The student demonstrations, which wracked both the United States and France, were particularly intractable to the dominant theories and were the most shocking for sociologists (Eyerman and Jamison, 1991). In many cases, the social scientists sided with activists and debated issues of strategy and tactics within protest movements. Their own experience made it difficult for social scientists to maintain the irrationalist assumptions of the collective behavior approach (Zald, 1992). Therefore a new tendency developed within social movement theory. Instead of separating collective action from the political as a distinct and irrational 'other,' social movements became seen as *part* of politics; as with the rest of the political process, social movements were seen to be pursuing political goals with means appropriate to their situation. Moreover, the events of France in 1968 in particular led to a new widespread concern among sociologists with 'cultural crisis' (cf Touraine et al., 1983: p. 6). However, Europe and the United States produced differing theoretical versions of these new 'rationalist' viewpoints in their responses to the new circumstances.

The Rise and Crisis of Resource Mobilization Theory

In the revolt against functionalism, North American social movement theorists sought to go beyond a purely macro-level focus. These social movement theorists were interested in the question why some grievances and not others developed into social movements. The RM approach arose as an answer to this question. What was distinctive about the RM approach was its attempt to theorize social movements in terms of the utilitarian, instrumental tradition – the complete obverse of the irrationalist assumptions of the old 'collective behavior' approach.

Some had been influenced by Olsen's (1965) rational choice theory of collective action (Mueller, 1992; e.g., Oberschall, 1973: pp. 114–117). In the collective behavior approach social strains had borne the explanatory weight for the emergence of collective action, whereas Olsen referred to measures of costs and benefits among individual members of the collective. Paralleling this, RM theorists argued that the extent of material and organizational resources available to a group were a better predictor of social movement mobilization than structural strains and subjective grievances. For example, Native Americans, blacks, and women mobilized only in the 1960s and the 1970s, even though strain and discontent among them had been relatively constant for many years (Mayer, 1991).

The logic of RM meant that the questions shaping social movement research became: what are the resources available for a movement, how are they organized, how does the state facilitate or impede collective mobilization, and what are the results of collective action (Mueller, 1992)? But many other questions that might be asked of social movements were necessarily excluded, in particular questions of identity and of psychological processes within the collective constituting that identity. The assumption of instrumental rationality led RM theorists to concern themselves only with the way preferences could be satisfied; the question of how such preferences might arise was not examined. Therefore, the discovery empirically of preferences being created or changed through collective action itself was awkward for RM (Scott, 1990). Analogously, Piven and Cloward (1991) raise difficulties for RM by pointing to examples of organization resulting *from* rather than *causing* collective action; for instance, in the 1930s, organizing committees were created among craft workers only after, rather than before, a wave of wildcat strikes. Piven and Cloward's argument is that the logical consequence of the attempt to counter the irrationalist approach to social movements by emphasizing instead the rational use of resources is that where RM theorists see a group acting *without* 'sufficient organization' (and this tends to refer in particular to the more oppressed or poorer social groups), this is defined as irrational and apolitical; hence the approval of many RM theorists for social movement leaders' attempts to quell rioting (Piven and Cloward, 1991). The same dichotomy posited by irrationalist theories between rational organization and irrational primitive groups is therefore reproduced; only the boundary dividing the two types has been moved.

The links that the 'collective behavior' and functionalist traditions suggested existed between psychological processes and irrationality had prompted RM theorists to react by developing an account of social movements without any social psychology at all. But the necessity of a social psychology might be said to be built into rationalism's own key problematic, that of the 'free rider': as a group member, the individual will necessarily gain from group action without having personally to take part in it; why then should anyone take part? The absence of compulsions or individual incentives in many instances of collective mobilization meant that the logic of RM was vulnerable to rupture by alien concepts such as identity and, latterly, meaning construction (Mueller, 1992).

Even from the start of its dominance, therefore, RM was under attack from critics for its overrationalized conception of social movements (Morris and Mueller, 1992). Instead of conceptualizing social movements purely as a function of organizational resources, critics argued that such (social psychological) concepts as grievances, ideologies, and identities had to be taken into account. Later developments from within the RM tradition therefore departed from the original framework in at least two ways (Mueller, 1992). First there was the claim that the actor viewed as an isolated *homo economicus* (following Olsen's metatheory), rationally calculating her action on the basis of givens in the social environment, should be reconceived in terms of her embeddedness in group identities of class, gender, nationality, ethnicity, and so on. Second, it was claimed that social locations overlap, providing not only resources and opportunities but also cultural material that actors may draw upon (together) to construe a sense of grievance. In contrast to both strain and RM, therefore, the new theorists wanted to stress that both grievances and resources are mediated by meanings; the meaning of social reality taken for granted by both these frameworks needed to be understood instead as contestable.

The 'New Social Movements'

While North American sociology had reflected the dominance of empiricism, among Europeans there was a greater willingness to embrace philosophical issues such as the political implications of theory (Eyerman and Jamison, 1991). Hence at the same time that Blumer's microsociology and the anodyne 'consensus' model of Parsons flourished on one side of the Atlantic, on the other side, the class conflict accounts of Weber and Marx remained foundational. Therefore in Europe, the emergence of the movements of the 1960s prompted a fresh engagement with these fundamental frameworks: did the nature of the new developments refute or confirm the traditional models of conflict?

Herbert Marcuse argued that a fundamental shift had occurred in capitalism, according to which NSMs were now at the center of social change, in place of the industrial proletariat (e.g., Marcuse, 1964; see Scott, 1990). Marcuse himself linked collective action with psychological change, by claiming that social transcendence required a transformation of the inner psyche (Flesher Fominaya, 2014).

As Scott (1990) argues, although most of the NSM theorists rejected Marx, their own frameworks echo the Marxist-influenced Marcusian account in which a substitute is sought for the industrial working class as an antagonistic and transformational agent. There is no full agreement on the referent of the term 'new social movements,' although there seems little disagreement that what distinguishes all those so described (for example, the women's, peace, and environmental movements) is their difference from the 'old' industrialized working class movements. This difference is what is important in the NSM perspective.

An example of an NSM study is Touraine et al.'s (1983) analysis of the French antinuclear movement. He notes that the movement began as a defensive reaction to fear of accident and ecological disaster. The movement ultimately collapsed, and Touraine's study was an attempt to understand why it did not develop into a movement with a wider

constituency. Touraine locates the movement's failure in its inability to clarify its own position in relation to technology and to define a clear enemy; the movement was unable to go beyond making a general critique and did not specify other modes of development. In this account, then, the failure or success of a movement to re-create itself and society in its own image stems from the failures of its ideology. The implication is that, given correct self-understanding and clear articulation of grievances, the enactment of change would flow automatically.

In Habermas's (e.g., 1978/1969) account, social movements are indicators of potential crises in late capitalism (Scott, 1990). What Habermas sees as the evolutionary process of 'modernity' entails the extension of rationality into all spheres of life. In the political and cultural realms, this satisfies the modern demand that policies be rationally presented and justified, but it conflicts with the role of the sociocultural system as a supplier of motivations. The NSMs are understood as an attempt to resist the 'inner colonization' of technical rationality while at the same time demanding increased levels of rational justification. Although Habermas's account includes the social transformational and self-changing potential of social movements, its emphasis is more on the wider social conditions that give rise to such movements than the processes within movements through which identity might emerge and change.

'Social Construction'

Klandermans (1992) suggests that, though the dominant social movement theory frameworks of previous years were in a sense complementary (RM explaining the *how*, and NSM examining the *why* of collective mobilization), in fact they shared a common deficit: neither of them explained what makes people define their situation in such a way that participation in a social movement seems appropriate. The turn to broadly social psychological issues of identity and meaning in social movement theory occurred on both sides of the Atlantic. Thus the concern with 'social construction' is common to a range of theories rather than a single theoretical perspective. Some key examples will serve to illustrate common themes and issues.

Although concerned with structural affordances in a similar way to RM theory, McAdam's (1982) account of the role of political processes also argues that such conditions and political opportunities can only explain movement insurgency in combination with the mediating role of processes of meaning attribution. McAdam explains changes in attribution in directions favorable to insurgency ('cognitive liberation') in terms of the altered responses by the members of a political system to a particular challenger, which serve to communicate to insurgents that the political system is becoming increasingly vulnerable to challenges. Similar to Piven and Cloward's (1977) three dimensions of transformation, McAdam suggests three types of belief for such a change: (1) the system is seen to lose legitimacy, (2) the system seems more capable of being changed, and (3) there is the sense that the person can change things. However, these changes are not simply 'read off' from the situation between insurgents and the political system; rather, groups of people jointly create the meanings that they read into current and anticipated events. Hence strong social integration within groups is a precondition of 'cognitive liberation' (p. 50).

Another influential social constructionist approach is Eyerman and Jamison's (1991) 'cognitive praxis' account, which conceptualizes social movements as forms of activity by which individuals create new kinds of knowledge and identities, both for themselves and for the societies in which they are situated. In a study of the new environmental movements in three countries in Europe, Eyerman and Jamison point to three dimensions of cognitive praxis: cosmological (the basic assumptions or beliefs about ecology shared by movement participants), technological (the specific topics of environmental protest, as well as alternative technologies such as renewable energy), and organizational (e.g., antielitism). They claim that environmentalism can only take the form of a social movement to the extent that the three dimensions are actively combined in the creation of 'new conceptual space' (pp. 68, 77); the European environmental activists managed this, and gave the issue known as 'the environment' new political and economic significance. In explaining this knowledge-producing and meaning-constituting process, Eyerman and Jamison suggest that, though all participants in a movement can contribute, some do so more than others; 'movement intellectuals' are those within movements that help create both their own roles and the very movements they participate in (p. 98). These individuals are able to publicly articulate the movement's identity through speeches, books, articles, and media appearances. They are not completely free to choose their moments and their arguments, however, but must do so in the context of counterarguments and in relation to the power of the media to recognize them. Both established intellectuals and those 'home-grown' within the movements become transformed through their involvement in these debates and arguments (p. 119).

In contrast to the early focus on crowds, Eyerman and Jamison's (1991) emphasis on movement participants' ability to define themselves and the world around them intellectually appears to render actual face-to-face collective participation explanatorily redundant in processes of meaning construction. Hence demonstrations, direct actions, and other crowd events are barely mentioned in their account (effects rather than causes of change?). This is a consequence of their focus; although the knowledge-producing activities of the movements are said to shape their own collective identities, the emphasis is very much on societal values rather than the particular ideas of movement participants. Identities change as a function of – or at least through the same process as – societal values: through the interplay between intellectuals and the wider public.

Melucci's (1989, 1995) account is a more explicit example of the social constructionist approach in the NSM tradition, and is said by some to be the most systematic and influential theory of collective identity in social movement theory (Flesher Fominaya, 2010a). Melucci argues that collective action should be understood as a process through which actors produce meanings, communicate, and negotiate; social movements are therefore themselves social constructions. Collective action is made possible through creating a 'collective identity' – a shared definition of the social world, shared goals, and a shared conception of the possibilities and constraints of collective action; collective identity is thus "the process of 'constructing'

an action system" (1995: p. 44). Groups can be more or less successful in creating a collective identity; without a collective identity, a group cannot accomplish collective action. Melucci therefore recommends that sociologists attend to the ways that social movements succeed or fail in becoming a social actor (1995): how are ends and means interpreted by different parts of the movement and what kinds of conflicts, tensions, and negotiations can be observed during the process of construction and maintenance of the collective identity? Collective identity as a process should therefore be a topic of social movement research rather than an assumption.

Unpacking 'Interaction' in Social Movement Theories

A common theme in a number of contemporary social movement accounts of meaning and identity construction is that of 'interaction.' But what does this mean in social psychological terms? Klandermans (1997) points out that concepts like cognitive liberation (McAdam, 1982), frame alignment (Snow et al., 1986), collective identity formation (Melucci, 1989), and others have all been proposed to account for meaning construction in mobilization but that they refer to different levels of meaning construction without being clear about this. He suggests that there is a neglect of the detail of face-to-face activity in collective action as part of these meaning construction processes (Klandermans, 1992). He links this absence with what he says is the failure of models such as those of Melucci and McAdam to combine the collective and the 'individual' (intragroup) levels of action and change. Implicitly at least, they depict 'flat' collectives and identities; the movements they describe seem untroubled by variation, and participants are therefore understood to change together consensually (Klandermans, 1992). Klandermans argues that transformation and change in collective beliefs should be linked theoretically to the possibility of individuals within the collective arguing against the dominant interpretation within their own group. Beliefs are contested, refuted, reformulated, and defended within as well as between groups; indeed, Klandermans suggests that (intragroup) deviation is inevitable.

Klandermans's (1992) own account of 'multiorganizational fields' is proposed as a way of grasping the relation between inter- and intragroup constructive processes in social movements through the role of structural vehicles. A movement's multiorganizational field refers to the total possible number of groups and organizations with which the movement might establish specific linkages, whether supportive or oppositional; these might include such things as friends, schools, churches, leisure clubs, and unions, and might be social category based (e.g., 'race,' gender, or class). Multiorganizational fields are always changing: coalitions collapse, controversies are resolved, organizations that were once competitors decide to join forces, new groups appear on the scene, and so on. It is through a community's multiorganizational field that grievances are interpreted, means and opportunities defined, opponents identified, strategies developed, and outcomes evaluated. Klandermans suggests that, in collective situations, the discussions that take place through social links enable people to clarify their relations with each other and with those they may be in conflict with: hence the 'us–them' polarization that occurs between groups in conflict (p. 98). Both within the group and outside it, different arguments vie for supremacy: "in the clashes and confrontations between competing or opposing schemes, meaning is constructed" (p. 100).

Klandermans (1992) sees studies by Hirsch (1990) and Fantasia (1988) as exceptions to the tendency to ignore face-to-face interaction in (sociological) social movements research, and their examples are used by him to illustrate the multiorganizational fields model. Both studies found increased solidarity during collective events (a student demonstration and wildcat strike, respectively) and a dramatic change in the worldview of many of the participants. In each case, participants were radicalized by the experience of collective resistance: they were more critical of the authorities, more willing to engage in the action as time went on, and more confident in the efficacy of such activities. Based on these kinds of findings, in Klandermans's account, 'discussion and argument' (e.g., p. 86) and 'interpersonal interaction' (e.g., p. 99) are assigned a central role, both within the collective itself and between participants and spectators. However, viewing this account from the perspective of mainstream theories of group processes and intergroup relations in social psychology, it is not clear that referring to these concepts resolves all the problems raised with other accounts of meaning construction. Thus, as a merely descriptive term, 'interaction' might refer to people acting both as relatively unique individuals or in their capacity as members of groups. As a social psychological explanatory concept, however, 'interpersonal' interaction is distinguishable in important ways from 'intergroup' interaction (Brown and Turner, 1981), since in the first people act on the basis of personal identities and in the second people act on the basis of social identities (Turner et al., 1987). It is an empirical question whether or not those 'interacting' in particular social movement contexts define themselves as unique individuals or group members, and what the psychological effect is of each type of interaction. To the extent that 'interpersonal interaction' is left unexplicated as a social psychological process, it still says little about what it is about movement participation that leads to identity change. While some more recent sociological social movement studies of the role of interaction have acknowledged the distinction between (inter) group versus personal levels of psychological functioning (Flesher Fominaya, 2010b), this has not been a widespread development in social movement theory.

The nature of 'discussion and argument' is similarly undertheorized. In his account of 'persuasive communications' in social movements, Klandermans (1992) observes that people are more likely to be influenced by members of their own group than by those they are opposed to. But what is the theoretical grounding? *Why* should some (group members') arguments and not others prevail, or even be listened to? Without specifying how and why particular social channels or conflicts enable or disable particular arguments among particular groups, an appeal to 'discussion and argument' does not go far beyond the accounts of Melucci (1989) and McAdam (1982), which, as Klandermans says, seem to refer merely to 'ideas' rather than social movement action.

The role of different types of interactions in transforming collective identities was examined in an ethnographic study of social movement development at an antiroads campaign (Drury et al., 2003). Here, it was only under certain conditions that 'discussion and argument' served to redefine collective identity boundaries such that participants in a 'local' protest came to see themselves as part of a 'global' social movement. Specifically, analysis of participants' accounts before and after involvement in the eviction of a tree suggested the role of conflict with the police in producing an oppositional definition of the collective identity, facilitating links to other groups in resistance to illegitimate authority. The analysis thus showed how intragroup interaction (among different protesters) could be put together with intergroup interaction (between protesters and police) to make sense of this process of identity creation. Particular 'within-group' arguments and speakers only became influential when relations *between* groups had changed. The aim to stop the road building from 'destroying Wanstead' was common to 'activists' and many 'locals' from the beginning of the campaign. But, to the extent that the 'activists' were defined as different from self, their arguments for the national and even global significance of the campaign were less easily accepted. The perceived violent eviction by police served to redefine *all* those involved – 'locals' and 'activists' alike – as sharing a common identity in relation to the police. Within this changed context, according to which the road building was clearly 'political,' the 'political' links made by protesters (to the national roads program and to state- and business-sponsored environmental destruction more widely) came to make more sense and the parochial construction of the issue was transcended.

A final point on 'interaction' is that in a number of social movement accounts it is said to transform collective beliefs through "necessarily a *gradual* process" Klandermans (1992: p. 85). For example, the collective identity necessary for people to be able to act together is said to be "constructed and negotiated through a repeated activation of the relationships that link individuals (or groups)" (Melucci, 1995: p. 44). Gradual or sustained psychological change over time is certainly important in the life cycle of social movements (Taylor, 1989). But, as with the extended processes of rumor and milling that Turner and Killian (1957) suggest account for the emergence of norms out of extraordinary situations' 'normlessness,' this way of understanding psychological change cannot account for the sudden transformations observed in many crowd events (Reicher, 1984).

Conclusions

A trend toward focusing on identity construction is a key example of the return of the social psychological in social movement theory, but it is not the only one. Another important development is increased interest in the role of emotion following years of neglect in response to the 'collective behavior' tradition (e.g., Goodwin et al., 2000). The focus on emotions is sometimes connected to identities and interaction (e.g., Jasper, 2010). This linkage parallels developments in social psychology, where intergroup accounts of emotion have developed within the social identity approach to explain intergroup behaviors (Mackie and Smith, 1998).

A second social psychological trend in social movement theory has been the development of 'impact' accounts, reflecting the empirical question of the durability of psychological and other biographical changes among social movement participants (e.g., Kiecolt, 2000). This has been studied in terms of participants' life history prior to involvement (e.g., Della Porta, 1992) and measured in terms of their subsequent opinions and activities (e.g., Fendrich and Lovoy, 1988). A common finding in these latter surveys is that, even 10 or 20 years after participation in social movements, former activists still differ from nonactivists on a variety of measures, including continuing to espouse left-wing views, remaining active in contemporary movements, and being involved in liberal professions, all impacts attributed to their participation in social movements.

Together, these developments and those outlined in the rest of this article show the continued relevance of social psychological issues in the study of social movements. This is the case whether the social psychological perspective has been applied directly (from social psychological theories) or indirectly (from other social science disciplines addressing topics that are broadly social psychological) and whether the processes of interest (identity construction, interaction, or emotion) are understood as part of the preconditions for social movement activity, a correlate of that activity, or its result.

Social Network Algorithms and Software

Ulrik Brandes, University of Konstanz, Konstanz, Germany

Abstract

Graph-theoretic concepts feature prominently in network analysis because they facilitate the exploration and assessment of structural properties in intuitive terms. However, they also pose algorithmic challenges not normally encountered in population statistics and attribute-based data analysis. We review efficient combinatorial algorithms for core problems of social network analysis and discuss important aspects of software for these tasks.

Introduction

Social network analysis is the application of network science on social networks, i.e., social phenomena are represented and studied by data on overlapping dyads as the units of observation (Brandes et al., 2013c). Consequently, graphs are a straightforward and convenient mathematical representation that will be the basis of this article.

The aspects by which to analyze graphs are very different from those of attribute tables and, thus, also require different approaches. It is inaccurate but instructive to think of this as a distinction between numerical or algebraic computations on the one side and combinatorial algorithms on the other side. Determining graph properties typically requires listing, counting, traversing, and constructing or decomposing structures instead of evaluating formulas or solving equations.

Combinatorial problems often have inefficient, brute-force solutions, and they can be a challenge to design, let alone implement, more efficient ones. Consequently, software for social network analysis may differ substantially in utility by the algorithms used and the types of analyses supported.

Here we review a number of core problems in the analysis of social networks and point out efficient algorithms to solve them. The focus is on problems that discriminate social network analysis from other forms of social data analysis and statistics. Hence, we do not cover problems such as dimensionality reduction, clustering, or simulation. They are treated extensively in other articles of this encyclopedia.

In a second, shorter part, we review a number of issues pertaining to software tools that facilitate the application of network-analytic techniques.

We start by making precise the input to subsequently discussed algorithms.

Graph Representations

Algorithms operate on precisely defined, symbolically represented input. We, therefore, need to define formally the objects that represent feasible input to the algorithms in subsequent sections.

A *graph* is a pair $G = (V, E)$, where V is a set of *vertices* (sometimes called nodes or points) and E is a set of *edges* (sometimes called links or lines). In a *directed* graph, $E \subseteq V \times V$ consists of ordered vertex pairs. In an *undirected* graph, the order does not matter, so that $E \subseteq \binom{V}{2}$ consists of two-element sets of vertices. If $\{v, w\} \in E$, vertices v and w are said to be *adjacent*. The set of all vertices $N(v) = \{w : \{v, w\} \in E\}$ adjacent to v is its *neighborhood*, and we define $N[v] = N(v) \cup \{v\}$. Moreover, let $N(S) = \cup_{v \in S} N(v)$ for any set $S \subseteq V$. Throughout this article, we denote with $n = |V|$ the number of vertices and with $m = |E|$ the number of edges.

There are more general classes of graphs, e.g., with multiple edges connecting the same pair of vertices (*multigraphs*) or more than two vertices in an edge (*hypergraphs*).

To concentrate on the main ideas and simplify the exposition, however, we will assume simple undirected graphs (i.e., undirected graphs without multiple edges or loops) throughout. While generalization to directed multigraphs is straightforward in most cases, valued graphs (i.e., graphs with vertex or edge labels) may require more sophisticated adaptation. In fact, most network-analytic concepts admit distinct generalizations to the valued case.

The two main criteria for the evaluation of algorithms are running time and memory requirements, and often there is a trade-off between the two. Both are expressed relative to the size of the problem instance, and, to eliminate the dependency on the actual implementation and hardware, both are specified in terms of their asymptotic growth rather than precise timings or operation counts.

Two standard data structures are the *adjacency matrix*, a two-dimensional array indexed by the vertices, and the *adjacency list*, an array containing a list of neighbors for each vertex. If a graph $G = (V, E)$ is represented in an adjacency matrix $A = (a_{vw})_{v,\, w \in V}$, then

$$a_{vw} = \begin{cases} 1 & \text{if } \{v, w\} \in E \\ 0 & \text{otherwise} \end{cases}$$

for all $v, w \in V$. Hence, we can test adjacency in constant time by inspecting the corresponding entry in the adjacency matrix. In an adjacency list representation, on the other hand, we have to scan the list of neighbors to test whether a vertex has a particular neighbor.

The *density* of a graph is the ratio of actual edges and potential edges. For an undirected graph, this is $\frac{2m}{n(n-1)}$, as there are $\binom{n}{2} = \frac{n(n-1)}{2}$ vertex pairs. Graphs representing social networks are often sparse, i.e., $m \in \mathcal{O}$ or $m \in \mathcal{O}(n \log n)$, so that the vast majority of entries in the adjacency matrix are zero and

the representation is not space efficient. Note that the percentage of entries representing edges tends to zero for growing n. Hence, at least in general, the adjacency list representation is preferred.

The following toy problem is used to illustrate the benefits of the sparse adjacency list representation and to introduce an important structural insight. A *two-mode network* represents pairwise relationships between elements of two disjoint groups such as the affiliation of persons with organizations. These are represented in *bipartite* graphs, where the vertex set is $V = U \uplus W$ and all the edges $E \subseteq \{\{u, w\} : u \in U, w \in W\}$ are required to be incident to vertices in both of the two disjoint sets.

A *one-mode projection* is the graph obtained by restriction to one of the two vertex sets and considering two vertices adjacent if and only if they have a common neighbor. In the above example, this could be a pair of persons affiliated with the same organization.

This operation is conveniently expressed in matrix notation. Using an adjacency matrix representation $A = (a_{uw})_{u \in U,\ w \in W}$, the two one-mode projections are obtained as AA^T and A^TA. Note that the product matrices actually contain the numbers of common neighbors and hence represent a valued graph; this can of course be binarized if desired. Straightforward matrix multiplication requires a cubic number of steps, but the results contain edges only where two nonzero entries are multiplied. With an adjacency list representation, these can be enumerated directly and exclusively.

An important observation for the evaluation of running times of algorithms that iterate over the neighbors of each vertex is that this is proportional to the number of edges and hence the number of nonzero entries in the adjacency matrix. Let $\deg(v)$ denote the *degree* of vertex v, i.e., the number of vertices adjacent to v.

Lemma 2.1 (Handshake Lemma) $\sum_{v \in V} \deg(v) = 2m$

We will use this relationship frequently yet tacitly to bound the running time of algorithms in simple terms. A straightforward example is determining all vertex degrees by enumerating the edges each vertex is incident to. This shows that, no matter whether vertex degrees are represented in the graph data structure, we can assume them to be given for; otherwise, we can always determine them in time linear in the size of the graph.

Algorithm 1: Sort vertices by degree (small to large)

```
input  : simple undirected graph G = (V, E)
output: array vert (vertices ordered by degree)
        vertex array pos (position in array)
        array bucket (Δ(G) + 1 buckets, initially 0)

// count vertices of same degree
for v ∈ V do bucket[deg(v)] ← bucket[deg(v)] + 1

// compute prefix sums (last index of each bucket)
for d = 1, ..., Δ(G) do bucket[d] ← bucket[d − 1] + bucket[d]

// place vertices in bucket intervals (back to front)
for v ∈ V do
    bucket[deg(v)] ← bucket[deg(v)] − 1
    pos[v] ← bucket[deg(v)]
    vert[pos[v]] ← v
```

Another observation that turns out to be very useful is that sorting the vertices of a graph by degree can be done faster than in the general case. While general comparison-based sorting algorithms require $\Omega(nlogn)$ time in the worst case, we can exploit the discrete and linearly bounded range of vertex degrees to sort in linear time. Let $\delta(G)$ and $\Delta(G)$ be the minimum and maximum degree of a graph G, then $0 \leq \delta(G) \leq \Delta(G) \leq n - 1$ and we can sort vertices by degree as shown in Algorithm 1. Note that the first position in an array is assumed to be 0, not 1.

Cliques and Cores

One of the earliest sociometric concepts is that of a *clique* (Luce and Perry, 1949). It corresponds to a subgraph of a simple, undirected graph in which every vertex is adjacent to every other vertex. A clique is the idealized version of a cohesive group.

Finding a clique with the maximum number of vertices in a graph is an $\mathcal{NP}$-hard problem (see glossary), but due to the absence of large cliques in empirical social networks even enumerating all inclusion-maximal cliques can be feasible. A clique is inclusion-maximal, if it is not contained in a larger one; hence, an inclusion-maximal clique cannot be extended even though, in general, it is not of maximum size. Before giving an enumeration algorithm, however, we consider one of the many relaxations that have been proposed because it can actually be determined efficiently, always.

An inclusion-maximal set of vertices is called a *k-core* (Seidman, 1983), if the minimum degree in its induced subgraph is at least k. It is easy to see that the k-core is uniquely determined and contained in the l-core for all $l < k$. Note, however, that k-cores need not be cohesive and, in fact, can even be disconnected. The maximum k for which a vertex v is contained in the k-core is called its *core number*, $core(v)$, and the maximum core number of any vertex is the core number of the graph, $core(G)$.

Algorithm 2: Core numbers

```
input  : simple undirected graph G = (V, E)
output: vertex array c (core numbers)

sort vertices by degree using Algorithm 1

for v ∈ V do c[v] ← deg(v)          // initial guess (upper bound)

for i = 0, ..., n − 1 do
    v ← vert[i]
    foreach w ∈ N(v) do
        if c[w] > c[v] then
            // get first entry in bucket
            u ← vert[bucket[c[w]]]
            if u ≠ w then
                // swap
                pos[u] ← pos[w];   pos[w] ← bucket[c[w]]
                vert[pos[u]] ← u;   vert[pos[w]] ← w
            bucket[c[w]] ← bucket[c[w]] + 1          // adjust boundary
            c[w] ← c[w] − 1                          // reduce estimate
```

Batagelj and Zaveršnik (2011) describe a simple algorithm to determine the core number of each vertex, which we adapt in Algorithm 2. After sorting vertices by degree, we can eliminate all vertices of minimum degree since their core number corresponds to that degree. Their elimination reduces the degrees of all neighbors and we can remove those as well if their

degrees fall below the previous minimum. Since each removal reduces only the degrees of neighbors and this reduction is by exactly one, the degree-based ordering can be maintained by exchanging such a vertex with the first vertex of the same degree; incrementing the last position of the preceding bucket, the vertex is effectively moved one bucket to the front. When there is no more vertex with a degree not larger than the previous minimum, we repeat the entire process with the new minimum degree as the core number for the next batch of vertices until the graph is empty.

Algorithm 2 requires linear time and space as well as scales to very large networks, independent of their structural characteristics. Note that when the algorithm terminates, the vertices are ordered by core number. Among all possible vertex orderings this is the one that minimizes the number of neighbors following a vertex in the ordering. This property is advantageous in several contexts, and we will make use of it in the algorithms for clique and triangle enumeration below.

Algorithm 3: Clique enumeration

```
input  : simple undirected graph G = (V, E)
output: all maximal cliques
begin
    // grow cliques from single vertices
    for v_i = v_1, ..., v_n ordered by core number do
        grow(N(v_i) ∩ {v_1, ..., v_{i-1}}, {v_i}, N(v_i) ∩ {v_{i+1}, ..., v_n})
end
grow(X, C, P) begin
    if P = ∅ = X then
        list C                                   // no more neighbors
    else
        choose any u ∈ P ∪ X                     // pivoting
        for v ∈ P \ N(u) do
            grow(X ∩ N(v), C ∪ {v}, P ∩ N(v))    // add v
            X ← X ∪ {v};   P ← P \ {v}
end
```

Let us now return to the problem of listing all maximal cliques. Algorithm 3 does so by recursively growing a clique C from each vertex v_i. A new clique member must be adjacent to all present members, and the same clique must not be listed twice. Therefore, a partition $N(C) = P \uplus X$ of the neighbors of C is maintained, where P contains vertices that are potential new members and X contains vertices that are excluded (such as those tried previously). Every time a vertex $v \in P$ is added to C, the candidates remaining in P are restricted to their intersection with $N(v)$. We have found a maximal clique C for the first time, if there are no more candidates ($P = \emptyset$, maximality) and no excluded neighbors ($X = \emptyset$, non-redundancy).

This general approach was proposed by Bron and Kerbosch (1973), but Algorithm 3 features two improvements that result in significant speedup. The first one is due to Tomita et al. (2006) and is called *pivoting*. It is based on the observation that, given some fixed $u \in N(C)$, no extension with a vertex from $N(C) \cap N(u)$ can yield a maximal clique without also including u or some other vertex from $N(C) \setminus N(u)$. This reduces the number of recursive calls. While it may seem that further improvements are obtained by selecting $u \in P \cup X$ such that $|N(u) \cap P|$ is maximum, our own experiments suggest that the required overhead is excessive because the following improvement already achieves some of the advantages implicitly.

This second improvement is due to Eppstein et al. (2010) and fixes the order in which vertices are used to seed the recursion. By starting from singleton cliques in order of nondecreasing core number, the cardinality of P, i.e., the number of potential extension, is never more than $core(G)$.

Triad Census and Clustering Coefficient

The *triad census* is a vector containing the number of occurrences of nonisomorphic subgraphs on exactly three vertices. For an undirected graph, these correspond to four graphs shown in **Figure 1**. Note that, by combination of different configurations in nonnull dyads, these are refined to 16 such subgraphs in the directed case. The triad census was proposed as a means to assess local structure (Holland and Leinhardt, 1970, 1976) and has been in wide use since.

Straightforward computation of the triad census requires classification of all $\binom{n}{3}$ combinations of three vertices and thus takes $\Theta(n^3)$ time. The fastest known approach, on the other hand, is based on an algorithm of Chiba and Nishizeki (1985), which lists all triangles (cliques of three vertices, T_3 in **Figure 1**) of an undirected graph G in time $\mathcal{O}(core(G)m)$. Since core number and average degree are generally low in social networks, this is near linear time.

The idea of Algorithm 4 is to orient the edges according to an ordering $v_1,\ldots,v_n$ of the vertices, so that every triangle becomes a transitive triad with a uniquely determined last vertex v_i. The sets of preceding and succeeding neighbors $v \in V$ are referred to by $N^-(v)$ and $N^+(v)$, respectively.

For each oriented edge (u, v_i), the other outgoing edges (u, w) of its source u are considered, and it is checked whether w is also a predecessor of v_i, so that u, w, v_i form a triangle. By marking and unmarking all predecessors u of v_i before and after, this test requires only constant time. Using the elimination ordering of Algorithm 2, each edge (u, v_i) is compared with at most $core(u)$ many others, giving the desired bound on the running time.

Figure 1 The four nonisomorphic graphs on three vertices.

Algorithm 4: Triad census

```
input  : simple undirected graph G = (V, E)
output: triad census T[0...3]
begin
    for i = 0, ..., 3 do T[i] ← 0
    for v_i = v_1, ..., v_n ordered by core number do
        T[2] ← T[2] + C(deg(v_i), 2)
        for u ∈ N^-(v_i) do mark u
        for u ∈ N^-(v_i) do
            for w ∈ N^+(u) do
                if w is marked then T[3] ← T[3] + 1        // triangle
        for u ∈ N^-(v_i) do unmark u
    T[2] ← T[2] − 3 · T[3]
    T[1] ← m(n − 2) − 2 · T[2] − 3 · T[3]
    T[0] ← C(n, 3) − T[1] − T[2] − T[3]
end
```

This triangle counting strategy is easily extended to yield the full census as follows. Every triad T_2 with exactly two edges has a unique vertex v_i of degree two. Pairing all $\deg(v_i)$ edges incident to v_i overshoots by counting each triangle three times (once each time v_i is contained in it). Since every edge forms a triad with each of the $n-2$ nonincident vertices, $m(n-2)$ counts every triad T_i once for each of the i edges it contains. Hence, the number of triads T_1 is $m(n-2)$ minus twice the number of triads T_2 and thrice the number of triads T_3. Clearly, the null-triads T_0 are all those that are not yet counted.

With a few additional case distinctions, Algorithm 4 applies to directed graphs as well. It can also be adapted straightforwardly to determine transitivity (triangle density), clustering coefficients (density of vertex neighborhoods), or constraint (Burt, 1992). Note that repeated counting of dyadic and triadic configurations is the computational bottleneck in probabilistic network models such as exponential random graph models (Lusher et al., 2013) or stochastic actor-oriented models (Snijders et al., 2010).

Role Equivalence

In contrast to Section Cliques and Cores, we now consider groups of actors defined by common structural roles rather than cohesion. See Borgatti and Everett (1992) and Lerner (2005) for background and an overview.

An equivalence relation $\sim \subseteq V \times V$ defined on the vertices of a simple undirected graph $G = (V, E)$ is called *structural equivalence* (Lorrain and White, 1971), if

$$v \sim w \Rightarrow N(v) = N(w)$$

for all $v, w \in V$. In other words, if two vertices are considered structurally equivalent, they have exactly the same neighbors. Any equivalence relation corresponds to a partition (into equivalence classes) and can also be represented as a *role assignment* r: $V \to \mathrm{IN}$, i.e., a function that assigns a role label to each vertex.

Algorithm 5 determines a role assignment based on structural equivalence that is maximum in the sense that every other partition into classes of structurally equivalent vertices is a refinement of this one. The algorithm is based on the straightforward observation that every vertex v is a witness for the nonequivalence of $w \in N(v)$ and $x \notin N(v)$. We therefore

Algorithm 5: Maximum structural equivalence

```
input  : simple undirected graph G = (V, E)
data   : integer array s (substitute role of neighbors)
         integer newrole (unused number)
output: vertex array r (role assignment)
newrole ← 1
for v ∈ V do r[v] ← newrole
s[newrole] ← 0
for v ∈ V do
    // assign neighbors to new role
    for w ∈ N(v) do
        if s[r[w]] = 0 then
            newrole ← newrole + 1
            s[r[w]] ← newrole;   s[newrole] ← r[w]
        r[w] ← s[r[w]]
    // clear substitutions
    for w ∈ N(v) do
        s[s[r[w]]] ← 0
        s[r[w]] ← 0
```

move neighbors w of v that had the same role i into the same newly created role $s[i]$, thus separating them from the non-neighbors. By linking the two role indices via s, we are able to reset this association in a second scan of the neighborhood of v. Note that after termination, the role indices that actually occur are in general not consecutive. By Lemma 2.1, running time is $\mathcal{O}(n+m)$.

The following is a concept of role that is based on relations to vertices that are equivalent rather than identical. An equivalence relation $\approx \subseteq V \times V$ defined on the vertices of a simple undirected graph $G = (V, E)$ is called *regular equivalence* (White and Reitz, 1983), if

$$v \approx w \Rightarrow N(v) \approx N(w)$$

for all $v, w \in V$, where two sets of vertices are equivalent if every member of one set has at least one equivalent member in the other set.

Every graph $G = (V, E)$ without isolated vertices has two trivial regular equivalences, $\approx\ = V \times V$ and $\approx\ = \{(v, v) : v \in V\}$, so that the maximum equivalence is not interesting. However, every partition of the vertices has a unique coarsest refinement that is regular, its *regular interior* (Borgatti and Everett, 1989).

Algorithm 6: Regular equivalence

```
input  : simple undirected graph G = (V, E), partition P of V
output: regular interior R of P
Q ← split(V, P)
R ← V
while R ≠ Q do
    find a block S ∈ R such that S ∉ Q
    find a block B ∈ Q such that B ⊂ S with |B| ≤ 1/2 |S|
    R ← (R \ S) ∪ {S \ B, B}
    Q ← split(S \ B, split(B, Q))
```

In other contexts, the regular interior is known as the *coarsest relational partition* and an efficient algorithm to determine it is given in Paige and Tarjan (1987). Similar to Algorithm 5,

Algorithm 6 is based on repeatedly *splitting* sets, which contain vertices with different roles in their neighborhoods. Given a partition $P = \{P_1,\ldots, P_k\}$ and a subset $S \subseteq V$ we define

$$spilt(S, P) = \{P_i \cap N(S), P_i \setminus N(S) : P_i \in P\}.$$

Note that $split(S, P) \preccurlyeq P$, i.e., splitting yields a refinement. It is important to note that the refinement obtained from a sequence of splits is independent of their order.

The sets P_i of a partition $P = \{P_1,\ldots, P_k\}$ are called *blocks*. A partition is *stable w.r.t. a set S*, if *split* $(S, P) = P$, and it is simply called *stable*, if it is stable w.r.t. each of its blocks. A stable partition corresponds to a regular equivalence and finding the regular interior thus corresponds to finding the coarsest stable partition.

A simple approach to find a stable refinement would be to choose any union of blocks as the next splitter until the partition is stable. Such an algorithm is correct because it maintains the invariant that the coarsest refinement of P is also a refinement of Q. The key to make the algorithm efficient is therefore the way in which blocks are chosen for splitting.

A second partition R is maintained that consists of unions of blocks of the current refinement Q. Starting from the entire set V, R is refined by splitting off blocks of Q, and the two subsets are tried as splitters of Q.

The algorithm maintains the invariant that Q is stable w.r.t. all blocks of R. This is asserted before the while loop, and whenever R is refined the two resulting blocks are used as splitters. Since $Q = R$ at termination, this implies that they are stable and that the algorithm is a specialization of the simple approach described above.

For efficiency, we maintain a list of the blocks in R that are unions of more than one block in Q and therefore qualify for the choice of S. Each of these *compound* blocks maintains a list of its blocks in Q. For every block $B \in Q$, a list of its member vertices and cardinality is maintained.

Observe that $split(S\backslash B, split(B, Q))$ results only in a three-way split of each block Q_i of Q. Since Q_i is stable w.r.t. S, the new blocks are $Q_i\backslash N(B)$, $(Q_i \cap N(B))\backslash N(S\backslash B)$, and $Q_i \cap N(B) \cap N(S\backslash B)$. It can thus be implemented by taking all neighbors of vertices in B out of Qi and classifying them according to whether all their neighbors in S are actually in B (this is what the cardinality counter is for). The entire split operation therefore takes only $\mathcal{O}(|B| + \sum_{v\in B}\deg(v))$ time.

Since B is always chosen as a smaller part of S, every vertex can be a member of a splitter B only $\mathcal{O}(\log n)$ times. The overall running time is therefore in $\mathcal{O}(m \log n)$, and the space requirement is linear.

Shortest-Path Centralities

Actor centrality indices in social networks have been classified along two dimensions (Borgatti, 2005): a diffusion mechanism (shortest paths, random walks, etc.) by which something (information, disease, etc.) spreads in a social network, and the nature of positions along the resulting pathways (beginning, center, etc.).

A *walk* in an undirected graph $G = (V, E)$ is an alternating sequence of vertices and edges such that edges appear only between their two end vertices. If no edge appears twice, the walk is called a *path*. A path starting from a source $s \in V$ and ending at a target $t \in V$ is called an (s, t)-path, and it is a *shortest* (s, t)-path, if it has the least number of edges among all (s, t)-paths. We use $d(s, t)$ to denote the length of a shortest (s, t)-path and refer to it as the *shortest-path distance* of s and t.

Two shortest-path centrality indices of common interest are

$$c_C(v) = \frac{1}{\sum_{t\in V} d(v, t)} \quad \text{closeness centrality}$$

$$c_B(v) = \sum_{s\neq v\neq t} \frac{\sigma(s, t|v)}{\sigma(s, t)} \quad \text{betweenness centrality}$$

where $\sigma(s, t)$ is the number of different shortest (s, t)-paths and $\sigma(s, t|v)$ is the number of shortest (s, t)-paths restricted to those passing through v.

Algorithm 7: Breadth-first search template

```
input  : simple undirected graph G = (V, E), source s ∈ V
data   : queue Q
output: vertex array dist (distance from root)
        vertex array pred (list of incoming edges on shortest paths)
for v ∈ V do dist[v] ← ∞
dist[s] ← 0
append Q ← s
⟶ init(s)
while Q not empty do
    extract v ← Q
    ⟶ settle(v)
    for e = {v, w} ∈ E do
        if dist[w] = ∞ then
            dist[w] ← dist[v] + 1
            append Q ← w
            pred[w] ← ∅
        if dist[w] = dist[v] + 1 then
            append pred[w] ← v
            ⟶ relax(v, e, w)
⟶ finish(s)
```

To compute these indices, we need to determine shortest paths and shortest-path distances first.

In simple undirected graphs, shortest-path distances are easily computed from a single source to all targets by breadth-first search (BFS). By itself, BFS is actually only a traversal strategy, and we have marked hooks in Algorithm 7 at which additional computations are typically performed. It should be clear how to determine closeness centrality of the source s by providing specializations of *settle* to add distances and of *finish* to invert the total.

Betweenness is a bit more challenging, but can still be obtained from the same template by introducing the derived relation of (*one-sided*) *dependency* $\delta(s|v) = \sum_{t\in V}\delta(s, t|v)$ with $\delta(s, t|v) = \dfrac{\sigma(s, t|v)}{\sigma(s, t)}$. Dependencies can be computed by an instantiation of BFS shown in Algorithm 8 and only need to be summed up to obtain betweenness centrality (Brandes, 2001).

In both cases, the running time is dominated by the n BFS traversals (one from each source) and thus in $\mathcal{O}(nm)$. Since the different BFS traversals do not depend on each other, overall space requirement is linear.

Algorithm 8: Source dependencies (specialized BFS)

```
data   : vertex array σ (number of shortest paths from source s)
         stack S
output: vertex array δ (dependencies of source s)
init(vertex s) begin
    for v ∈ V do
        σ[v] ← 0
        δ[v] ← 0
    σ[s] ← 1
end
settle(vertex v) begin
    S.push(v)
end
relax(vertex v, edge e, vertex w) begin
    if length(pred[w]) = 1 then          // one predecessor only?
        σ[w] ← σ[v]
    else
        σ[w] ← σ[w] + σ[v]
end
finish(vertex s) begin
    while S ≠ ∅ do
        w ← S.pop()
        for v ∈ pred[w] do
            δ[v] ← δ[v] + (σ[v]/σ[w]) · (1 + δ[w])
end
```

Software

While it is not unusual that analyses are scripted in general statistical software, few social network analysts will be implementing graph algorithms such as the above.

A variety of dedicated software tools is available in which the basic tasks of data management, analysis, visualization, and interactive exploration are addressed to varying degrees. Quite frequently, however, the algorithms implemented are not the most efficient.

In addition to fairly comprehensive tools with a graphical user interface, library implementations provide selected algorithms and functionality for adaption in one's own programing project. In some cases, useful functionality might also be available in tools that have been created for different purposes such as the analysis of molecular structures.

We are not going to discuss specific software in this article because a short discussion cannot do justice to the complexity of such tools, and is quickly outdated anyway. Instead, we review some general criteria on how to evaluate the utility of software.

Data

The generality of network representations and diversity of application scenarios have led to the coexistence of a huge variety of data formats, many of which are associated with one particular software. These formats differ not only in their syntax, but quite severely in their expressiveness. For software that does not support handling of certain network representations, such as longitudinal networks or collections of personal networks, it is likely that the associated format is not capable of representing them either. This is often a deliberate choice in order to ease the requirements for parsing the format.

In software for the analysis of social networks, data management is usually aligned with a default network representation. These are almost exclusively either matrices or graphs, so that most common formats for storing network data are comma-separated values tables for adjacency lists, adjacency matrices, and attribute tables, and an XML-based format for attributed graphs and hypergraphs such as GraphML (Brandes et al., 2013a). There are, however, numerous other, often proprietary, formats so that the transfer of data from one tool to another may require (possibly lossy) conversion.

As a general rule, it is good to have data available in tables representing adjacency matrices, edge lists, or attributes for archival purposes and data exchange. This includes computed indices, layout coordinates, and other information that may be of relevance for documentation and exchange. An expressive format that allows to represent various types of networks including longitudinal networks, hypergraphs, and network ensembles along with data attributes and graphical properties will ease data management and documentation substantially. Due to the lack of a common specification for graphical appearances, tools nevertheless have to support mapping of data attributes to graphical features.

An important consideration beyond supported data formats is data transformation capabilities. Most software tools will support, say, one-mode projections of two-mode networks. For exploratory analysis, however, even simple operations such as reorientation of edges, filtering, thresholding, hiding, copy & paste, or transformation of attribute values may be important. Although most of them are easily performed outside of a network-analytic software tool, this may require more technical expertise and is almost certainly less convenient.

Analysis

Quite a few software tools offer implementations of methods for the full range of analytic tasks except statistical modeling, for which dedicated software exists.

They differ substantially, though, in the variety of methods for the same task.

While most tools, e.g., allow for degree, closeness, and betweenness centrality computation, other common (e.g., eigenvector centrality, Katz's status, PageRank) or less common (e.g., β-centrality, random-walk betweenness, information centrality) indices may be available in selected stand-alone applications or libraries only. This applies even more to methods for cohesive groups and role equivalences.

In addition to comprehensiveness, efficiency may be an important criterion. As this article demonstrated, many network-analytic problems have simple, easy-to-implement solutions that are highly inefficient, whereas the design and implementation of efficient algorithms may require more effort and expertise. When the practical running times of a tool are too slow for repetitive or large-scale analyses, it is not necessarily the case that this applies to all other tools as well. A seemingly out-of-scope analysis may indeed be practical in another tool.

A similar concern is the level of generality at which methods are made available. Most procedures are parameterized, but the degree to which parameters can be controlled may vary. Similarly, generalizations of procedures beyond their original definition, say for connected binary (i.e., unweighted) networks, may or may not be available.

Finally, a rarely mentioned concern is accuracy. Combinations of data and algorithms can yield tricky cases or numerical computations that lead to flawed or imprecise results. Since there are no established procedures for assessing the accuracy of tools for network analysis, it is wise to cross-validate important and surprising results with multiple tools – although it should be clear that it is not necessarily the majority that is right on a specific task.

Visualization and Interaction

Social network analysis benefits tremendously from informative and attractive visual representations. This applies to both the discovery and communication of results.

Depending on the research question, available data, and usage scenario, different representations may be preferable (Brandes et al., 2013b). Software with strong analytic capacity, however, is most often limited to conventional representations with pointlike nodes connected by linelike edges. Even matrix representations are rarely supported, and only selected tools offer dedicated representations, for instance, for hierarchical clustering, two-mode networks, or event networks.

An underestimated aspect in network visualization is the effect of a network layout. Even though crisscrossing lines convey an air of detailedness and complexity, their effect on accurate and unbiased information display is mostly deteriorating. Due to the subtleties involved in the design and implementation of proper layout algorithms, however, many tool designers choose to revert to simple, established, and accepted algorithms, most notably the spring embedder of Fruchterman and Reingold (1991).

Social network studies differ in so many respects that it is implausible that some standardized representation and layout algorithm ignoring the analytic perspective are capable of providing the most appropriate visualizations. The survey of Brandes et al. (2013b) may serve as an inspiration regarding possibilities, including some concrete software. Researchers should not look for fancy graphics but analyze the suitability of visualization designs for their purposes.

Compared to other areas, the provision of interaction techniques for network data analysis and exploration is limited. While the possibility to change node positions and edge routing, label placement, or colors, sizes, and shapes is relatively common, little support is provided for view transformations such as focus and context or selective and linked views. Similarly, data transformation is initiated mostly via menu items or control panels.

Given the diversity of social network studies, it is unlikely that a single tool will suffice for the majority of purposes. As of now, the individual requirements on data management, analysis, and visualization may be served best by a specific combination of tools.

Abstract

In this article we describe the analytic method of social network analysis (SNA). Specifically, we outline the foundations of SNA, key concepts and metrics, and current applications of SNA in areas of applied social and behavioral sciences. These areas include health studies, education research, organization research, team science, and information dissemination. As such, this article acts as an entry point into this method and a potential reference resource for individuals interested in exploring a deeper understanding of SNA.

Social network analysis (SNA) is used for measuring and analyzing the structural properties of networks of interdependent dyadic relationships. Such relationships can be interpersonal relationships like advice seeking, friendship, or trust that characterizes interactions between individuals; or interorganizational networks that characterize the relationships between organizations as a whole – including relationships, such as joint collaborations, resource exchange, information exchange, or even membership in common organizations (e.g., trade associations). One of the core assumptions of SNA is that the patterns of these relationships can have important effects on individual and organizational behavior, constraining or enabling access to resources, and exposure to information and behavior.

That assumption comes from the fact that society is composed of groups of individuals interacting with each other in social relationships. Through the accrual and persistence of such relationships social norms, culture, and institutions take shape. Critical to this process and, as such, to society, are the patterns and structures of social relationships, termed social networks, which provide constraints and opportunities for individuals to engage and influence their social world (Simmel, 1950[1908]; Frisby and Sayer, 1986). For example, the relationships among hospital staff (e.g., physicians and nurses) shape the provision and quality of care to patients. In schools, the relationships among principals, teachers, and parents are vital to the quality of education of students. And in scientific research, we increasingly see the importance of research teams working collaboratively in networks of social relationships for the production of rigorous research (Falk-Krzesinski et al., 2010).

SNA is used to study the structures of relationships such as those listed above by linking individuals (or other social units, such as organizations) and modeling interdependencies in behavior or attitudes related to configurations of social relations (O'Malley and Marsden, 2008). As such SNA can be a powerful technique for researching social phenomena such as the flow of information in a social network and the coordination, cooperation, or trust among groups of people. Just like any other social research procedure, we can use SNA to discover vital descriptive and inferential information about such social phenomena.

The import of SNA for applied social and behavioral sciences is also evidenced in the above examples. Education research, health research, and team science are three of many areas of study in applied social science. SNA allows researchers to understand the interrelationships that are crucial to such fields, for example, allowing us to identify the key actors related to professional development in a school system, to describe the amount of communication among medical professionals at a hospital, or better understand the collaborations created by a research initiative.

Social networks are at the core of our existence and due to the inherent interdependency of observations in social relationships; social networks require a specialized method of study. SNA is that method for describing, analyzing, and understanding social relationships. In this article we will review the foundations of the method, key concepts and metrics, and current directions in the use of SNA in areas of applied social and behavioral sciences.

Background

The concept of a social network can be traced back to the work of Simmel (1950[1908]) whose ideas on social distance, groups, dyads, and triads represent the foundation of SNA. These ideas were extended and operationalized by Moreno (1953[1934]) using graph theory and relational algebra to create the first social network graph and analysis. Advances in SNA have since produced a vast array of concepts, measures, and techniques. For a detailed look at such concepts and measures see Wasserman and Faust (1994), Scott (2000), Carrington et al. (2005), and Hanneman and Riddle (2005). In the following subsection, we briefly cover the basic concepts and measures of SNA needed to get newcomers started in the method.

Concepts and Measures

To begin, every social network includes *nodes*, *relationship*(*s*), and *ties*. (In the social network literature, nodes have also been termed actors and vertices, while ties have also been termed connections and edges. All are excepted terminology

referring to the same respective concepts.) A node represents the network members which can be individual persons or collective groups (e.g., boards of directors, social groups, clubs, or businesses). Relationships in a network are the basis on which nodes in a network are connected (e.g., friendship, collaboration, trading goods or services, or passing information). And a tie represents a connection between two nodes on the basis of a given relationship. Note that a relationship, and as such ties, can be *directed* (e.g., passing information) or *undirected* (e.g., joint collaboration). Also, there may be multiple types of relationships existing between the same set of nodes (e.g., there may exist, simultaneously, friendship, romantic, and collaboration networks among a set of coworkers at a business). The smallest social network possible is the *dyad*, a network containing two nodes with a single tie between them (see Figure 1). A dyad is not necessarily very interesting, but does represent the building block of larger networks. If a third node is added to the network and ties are made between each pair in the group, a triad is formed (see Figure 2). From there, larger networks of expanding size and structural complexity are formed (see Figure 3). Such larger network structures are typical of those studied in SNA and upon which SNA measures are utilized to describe and evaluate.

The unit of analysis in SNA is the tie and the data for a given social network are the ties that exist among a set of nodes. As such, social network data are interdependent – the connections for one node are directly related to the connections of other nodes in a social network. Two consequences of this fact are that (1) data must be entered into a *matrix* rather than a traditional format, and (2) traditional statistical analyses are not necessarily applicable to network data. To exemplify the first point, consider the collaboration network that has been created for the writing of this article – Mike, Atsushi, and Maura are the nodes in this collaboration and they are tied together based on their joint work. Table 1 demonstrates the data matrix for such a network and Figure 4 is the graphical representation of the network.

The example above is an undirected network. If we change the data in the matrix and thereby the network graph, we can see what a directed network looks like – in Table 2 and Figure 5 the relationship might be information sharing with ties representing incidents of sharing information.

Network data can be *egocentric* or *sociocentric*. Egocentric network data are collected from the perspective of a focal node or set of nodes. For example, survey respondents could be asked to list their friends. In this way a friendship network is constructed, however, the friends listed would not have an opportunity to confirm their tie to a respondent or list other ties they have. Sociocentric network data are a complete record of all ties among a bounded set of nodes. Clearly, more complete data are better, particularly for social networks. However, often complete network data are too difficult to obtain and we must rely on egocentric data. Another consideration is tie value, whereby ties in a network may be coded simply as binary (present or absent) or valued based on some scale. And lastly, there may be multiple *modes* in a social network, which occurs when there are multiple sets of nodes in the same network (e.g., persons and organizations).

Figure 1 Dyad social network. Note: graph created with NodeXL.

Figure 2 Triad social network. Note: graph created with NodeXL.

These pieces of information are the basic elements required for SNA. From here we can briefly discuss some social network measures which can be at the node level or the network level of analysis. Node-level measures are utilized to describe and examine the nodes of a network. Here characteristics of the nodes can be layered into the analysis as node-level measures. Another node-level measure, and perhaps the key one, is centrality. Centrality can be calculated a variety of ways and is used to identify key or central nodes in a network. *Degree centrality* is determined by the number of direct connections to a given node. *Betweenness centrality* finds that nodes fall between other nodes most often and is useful in finding places where a network would break off if a node with high betweenness was removed. And *closeness centrality* measures the reach of a given node or rather how close a given node is to others in a network. Closeness can be particularly meaningful in directed networks concerned with flows or disseminations of information, material, or disease. Lastly, with regard to node-level analysis, *distance* or *path* is a measure of the minimal number of ties between two nodes or the degrees of separation between two nodes. Distance is foundational to all node-level measures and can be used at the network level of analysis to describe the overall size of a network.

Network-level measures are utilized to describe and examine the overall structure of a social network and are often referred to as measures of network cohesion. *Density* is perhaps the most utilized network-level measure. Density is the proportion of the actual number of ties in a network to the number of possible ties in a network. Higher densities mean more interconnectedness among the nodes in a network. *Reachability* simply measures whether a node can reach all others in a network, directly or indirectly. *Distance*, as noted above, can be used at the network level such that the largest distance in a network represents its diameter and the average distance in a network gives us an overall sense of how separated most nodes are from each other. Similarly, average centrality can be calculated for a network to determine how centralized a network is, which determines if most ties belong to a small set of nodes or are divided more evenly across nodes. Furthermore, *subgroup* analyses can be conducted at the network level to determine if there are meaningful *clusters* of nodes separated throughout a network, which, like closeness, can be important regarding flows in directed networks. Lastly, note that calculations and interpretations of these SNA measures (e.g., centrality, distance, density, and subgroup clustering) will vary if ties are valued or directed.

Figure 3 Example social network. Note: graph created with NodeXL.

In this section of the article we have briefly reviewed the basics of SNA. Next we turn to applications of SNA, dividing our review of applications by the types of analysis possible – node level, network level, and flow analysis.

Current Applications of SNA

In this section we describe some current applications of SNA to demonstrate the utility of SNA across areas of applied social and behavioral sciences. These areas include the study of team science, health research, education research, and organizational research. The section is broken out by types of network analysis to assist readers in understanding how SNA was utilized in each example. The focus in each subsection is on examples of applications rather than methodological details. Again, for more detailed information on the methods behind SNA measures and metrics, see Wasserman and Faust (1994), Scott (2000), Carrington et al. (2005), and Hanneman and Riddle (2005).

Node-Level Analysis

Node-level SNA focuses on the individual actors or nodes in a network and to an extent the small groups those nodes form in the larger network. Measures and metrics for node-level analysis center on the characteristics of nodes within a network, distance to determine the 'degrees of separation' between two nodes in a network, and centrality measures (e.g., degree, closeness, betweenness) to locate key nodes in a network. Node characteristics can be any categorization of the individuals within a network, such as persons' race, educational attainment; status as smoker or nonsmoker; role as a leader or follower; or condition as having a disorder or disease. Relational ties in a social network can be related to such node characteristics.

For example, Valente et al. (2005) examined the friendship patterns and smoking behavior of sixth and seventh graders across middle schools in southern California. They found popularity, as determined by network centrality, to be associated with increased susceptibility to smoke and smoking. Popular students were more likely to become smokers compared to less popular students. Such results point to the importance of understanding social networks and SNA for smoking prevention initiatives. Similarly, in examining the membership network of the National Network Consortium on Tobacco Control in Priority Populations, Luke et al. (2010) found that organizations' geographic location and status as a lead agency impacted the likelihood of connections among members. Specifically, individuals were more likely to connect if one was from a lead agency and more likely to connect if individuals were geographically close to one another.

Exploring organizational support for nutrition assistance programs at farmers markets, Dixit-Joshi et al. (2013) used organization type (e.g., federal government, state government, foundation, etc.) to describe and understand which organizations tend to support nutrition assistance programs offered by farmers markets across the United States. In another example, Liu et al. (2010) studied the relationship between social influence and rising autism diagnoses. Specifically, they found that children living very near to a child with autism are more likely to also be diagnosed with autism. They explain this result as the consequence of parents' interactions in social networks – one parent has a child diagnosed with autism, then shares their experience with others, who then are able to recognize similar autism markers in their own children. And Christakis and Fowler (2007) found that a person's chances of becoming obese were higher if they were friends with another person who became obese over a given period. Suggesting obesity, to an extent, spreads through social networks.

Centrality measures, such as degree centrality, betweenness centrality, and closeness centrality are utilized at the node level to identify important individuals in a network. Doing so can have important implications for future research, policy making, or planning. For example, evaluating the knowledge capacity of the Hydrogen Initiative Program at the Idaho National Laboratory, Birk (2005) utilized SNA to explore the network of advice and information seeking relationships in the program. She revealed that there existed a handful of individuals with high-degree centrality that the rest of the network relied on for information and advice. As such, Birk suggests that the loss of these individuals could create a void in the knowledge capacity of the program.

Additionally regarding centrality, Provan et al. (2010) examined the collaboration network among organizations in the Arizona Cancer Coalition. These organizations could be involved in any combination of three types of research networks (discovery, development, and/or delivery). The researchers found that high-degree centrality in the discovery and development networks were positively correlated to the importance of cancer research to the organization. Similarly, Leischow et al. (2012) found that among quitline organizations in the North American Quitline Consortium (NAQC), betweenness centrality was a critical measure of an organization's importance related to the sharing of best practices.

Figure 5 Directed collaboration network. Note: graph created with NodeXL.

Fredericks (2005) evaluated a developmentally disabled demonstration program designed by a state agency to optimize services and supports (e.g., early childhood development centers, day care, and universal pre-K) to consumers using existing sites. She found a small group of five organizations were highly central, with the highest degree and closeness centrality, in the information sharing network and represented a 'core' group integral to the function of the program.

In evaluating the implementation of a collaborative learning environment program for a Master in Public Administration (MPA) Program, Kapucu et al. (2010) used SNA to examine degree and closeness centrality measures for class friendships and shared class work among students pre- and postimplementation. They found that the program increased degree and closeness centrality across students in both the friendship network and class work network, suggesting the benefit of the collaborative learning program. And Hawe and Ghali (2008) studied the use of network analysis to model the social structure of high school staff and teachers in order to facilitate a school-wide health promotion intervention. They found betweenness centrality to be the most important measure for identifying individuals that can help expand the reach of their health promotion intervention. Specifically, individuals with high betweenness act as bridges or gatekeepers to the periphery of the network, while individuals with only high-degree centrality may not be able to reach others on the periphery of the network.

And Malinick et al. (2013) examined the relationship between social movements and media coverage using centrality in a two-mode network analysis. In this study, researchers employed a two-mode network strategy to evaluate the relationship between environmental activists' individual attributes and their centrality in the environmental movement's communication network. They found that being in a leadership position had very little to do with their centrality in the movement's communication network. However, they found clear evidence between centrality and media coverage. Based on these findings, they concluded that in the social movement, the strategically placed individuals, rather than the leadership, carry the responsibility of communicating with the media to spread and draw critically needed attention to their cause.

Regarding distance in SNA, this measure can be viewed as a node-level and a network-level measure. The distance between two nodes in SNA, as indicated earlier, is represented by the minimal number of connections that exist between them (i.e., six degrees of separation as popularized in media). At the network level, the maximum distance found in a social network represents the diameter of that network. At the node level, distance is a simple measure of how far apart the nodes are in a network. For example, Newman (2001) studied the scientific collaboration networks formed via coauthorships in scholarly publications. Newman posited that such networks are 'small worlds' (Milgram, 1967; Travers and Milgram, 1969) in which collaborators are part of tightly knit smaller groups and yet are

individually only a short distance from any other member of the network. He used average distance for the network to partially address this hypothesis, finding that scientific collaborators were indeed, on average, short distances from one another.

In this subsection we have reviewed recent applications of node-level measures in SNA, particularly node characteristics, centrality, and distance. Conveniently, the measure of distance brings us to the next subsection of this article – network-level measures in SNA.

Network-Level Analysis

In this subsection, we review applications of SNA measures at the network level of analysis. As mentioned previously, in using SNA we can apply a variety of measures to a network of interest. At the network-level of analysis, we attempt to uncover and describe the overall distribution of relations among nodes, instead of focusing on examining the attributes of individual nodes. For example, we might examine the density of the network, the size of the network, the number of subgroups in a network, or the average degree, betweenness, and closeness centrality of a network. Additionally, we can look at how the structure of a network changes over time or how the network structures of two groups or organizations of similar size compare to each other.

Examples of the use of density and average centrality in applications of SNA include the examination of friendships in classrooms (Kapucu et al., 2010) mentioned previously, the assessment of the role of networks in obesity prevention among day care centers (Marks et al., 2013), and the previously mentioned study of collaborative network involvement among 18 organizations within the Arizona Cancer Coalition (Provan et al., 2010). In examining the effect of collaborative learning in MPA program at the University of Central Florida, Kapucu et al. (2010) assessed the friendship network at the beginning and end of the school term. The average degree and closeness centrality measures were used to describe the significant increase in friendships and class work partnership, concluding that this increase would stimulate collaborative learning.

In assessing whether relational structures among child care workers play a role in obesity prevention, Marks et al. (2013) compared average centrality measures from network data that identified who provided dietary, physical activity, and policy information, who was involved in dietary decision-making with whom, and who consulted with whom on information for dietary and physical activity planning. The analysis showed staff interrelationships about physical activity, dietary, and policy information played key roles in each day care center. Additionally, they found that the network density varied for each day care center, suggesting that the SNA enabled the identification of unique center social dynamics. And as such, these differences could potentially be used to build future team capacity within the centers.

In studying collaboration in a cancer research network, Provan et al. (2010) used network data to describe the structure of network relations among cancer research organizations. They modeled network relations in three dimensions of research activities and measured the extent to which collaboration occurs within or across these three dimensions of research activity. They utilized overall network centralization and density to describe and compare the distribution of ties in the network and the overall connectedness of the network.

Another commonly used analysis at the network level is the identification and examination of network subgroups or substructures, sometimes referred to as clusters or clustering. Clusters refer to interconnected subgroups in a network and often can be displayed visually as regions in a network with relatively high local density and relatively few links to other clusters (Hoppe and Reinelt, 2010). Uncovering such subgroups in a network can be highly useful in applied fields. For example, Girvan and Newman (2002) used betweenness centrality to identify clusters of scientists in the larger collaboration network at an interdisciplinary research center at the Santa Fe Institute. These 'communities' centered on scientists' research topics or methodologies.

Hypothetically, in a leadership network, we could examine if the structures of network connectivity enable efficient sharing of information sufficiently and if the network effectively bridges clusters. Density and betweenness centrality are useful measures to detect and recognize the clusters. These measures offer important information about the connectivity among actors as well as clusters. For example, in the previously mentioned study of the NAQC, Leischow et al. (2012) discovered clear clusters representing the United States and Canada, and found a few quitline service providers had particularly high betweenness centrality and acted as leaders in sharing information. These findings suggested that although considerable amounts of communications and information sharing were occurring across the quitline service providers, the communication and information sharing patterns were not occurring equally – functioning as a type of coalition or community. They concluded that how the quitlines share information to improve practice will become increasingly important as quitline use expands.

Lastly, returning to Newman's (2001) study of scientific collaboration networks, he utilized the total number of collaborators and ties in the network, the maximum distance between collaborators of the network, and the average distance between collaborators to demonstrate the small world character of the network. These collaboration networks were huge in size, but there were relatively small average distances between collaborators. These patterns suggest that the network was characterized by significant clustering with a smaller number of bridges joining clusters of collaborators and conclude that such features are crucial for the development and functioning of a scientific community.

In this subsection, we discussed SNA measures at the network level. Specifically, SNA has been used in applied research to evaluate the networks of specific relational content. SNA is employed to study the networks of relationships among individuals, organizations, or social events and measures such as average centrality, density, and distance are used to describe and make inference about the larger network structure. In the next section, we discuss how SNA can be utilized to study flows of information, physical items, diseases, and ideas through networks.

Flow Analysis

In addition to describing static property, SNA has been used to model and explore how information, attitudes, or physical

items spread through network connections. All of these possibilities involve directional ties, as discussed in the background section of this article, but flow analysis additionally depends on the properties of actors, ties, and the ideas or items being transmitted. Considerations include (Borgatti, 2005):

- Can an actor be part of a path exactly once or more than once? A disease or infection that leaves the host immune cannot reach an actor more than once, while a physical item may travel to the same actor multiple times.
- Can a path be traveled exactly once or repeated? Some physical items, such as a loaned book, follow a path exactly once, while others, such as currency, can repeat a path.
- If a directional path connects actors A and B, can a directional path also connect actors B and A? A physical item can be returned, traveling from actor A to B and back to A, while a piece of information would not reverse its path.
- Do transmissions connect one actor to only one other actor, or can one actor connect to multiple actors? A physical item cannot travel from actor A to both actors B and C simultaneously, while a piece of information can duplicate itself and reach both B and C.
- If duplication occurs, are copies identical or merely similar to the original item? In a chain of e-mail forwards, simultaneous recipients read the same, replicated information. The spread of a virus reaches multiple recipients, but mutations and variations occur in the process.

Findings of network-level analysis may differ depending on the rules that govern flow. Simulations show that measures such as centrality, closeness, and betweenness may yield different results across different path restriction rules (Borgatti, 2005). As such the use of these measures should include consideration of whether closeness, for example, is truly capturing the distance or time by which goods or information travel from actor A to actor B.

In order to describe or analyze flow through a network, analyses also depend on the type of data collected. Researchers and evaluators may collect information directly from actors in a network by conducting a survey, or they may rely on secondary data or network information, if such data is tracked and accessible. Electronic communications provide an excellent opportunity to track the transfer of messages or information. Studies have used secondary data regarding online communities or message boards (e.g., Usenet, special interest groups), social networking Web sites (e.g., Twitter, Flickr), and e-mail messages (e.g., internal messages within a company or university). For example, Kumar et al. (2010) collected data from Usenet groups, focusing on message boards on a variety of subject matter areas, to track how conversations spread among their members. Members create original posts or reply to existing posts, creating branching conversation threads. Research focused on comparing conversation trees within networks (e.g., the size and depth of conversation trees), as well as how these features varied with the presence or absence of prolific, highly connected posters.

In order to explore how quickly and widely information spreads over a social networking Web site, as well as the role of friendship ties in this dissemination, Cha et al. (2009) used data from the Web site Flickr. This Web site allows users to upload photos, link to, or comment upon other users' photos, and create ties with other users. Rather than analyzing the entire network, the size of which could be classified as prohibitively large, analysts used a snowball sample in which they randomly selected users, and then branched out their initial sample by including other users to which their sample was connected, repeating this process over the data collection period. Similarly, Wang et al. (2011) used internal corporate e-mails over 2 years to explore the ways in which employees forwarded messages to their colleagues. Analysis of the flow of e-mails focused both on individual actors, for example, how quickly an actor spread information and to whom it was sent, as well as the entire network, for example, the structural properties of the flow network and the best models with which to explain the flow process.

When secondary data records are unavailable, either due to limited access to such data or its lack of existence, survey, and other self-reported information can help to describe the flow of information through a network. For example, in a study measuring communication within a lab group, Haythornthwaite and Wellman (1998), sought to explore how the relationships, both professional and personal, related to the frequency and modes of contact between its members. While some of this information might be available from secondary sources, for example, e-mail exchanges within a professional setting, researchers would be unlikely to have access to records detailing e-mail exchanges through external accounts, telephone exchanges, or in-person exchanges. In addition, capturing e-mail conversations only measures whether a message was sent from actor A to actor B, but the type of exchange, such as whether the message is a directive, a collaborative conversation, or a social discussion, is rarely available to researchers. Instead, network members were asked to report the number of times within a time period on which they received an assignment from another member, gave an assignment, and other types of transitive interactions based on their own judgments and recollections.

The considerations and studies laid out above have important implications for applied research on flow networks. For example, Burt (1987) studied the flow of medical innovation, specifically prescription of new drugs, through a network of physicians. He found that the dominate factor in the flow of medical innovation in this network was personal preferences among physicians, not their network position. While Valente and Davis (1999) used simulations of a communication network of physicians in an Illinois community to suggest that opinion leaders (identified via centrality) are crucial for the diffusion and flow of medical innovations in the network. For a wider review of other studies on flows and diffusion, see Strang and Soule's (1998) review focusing on the structural and cultural influences on diffusion processes.

Conclusion

In this article we gave a brief overview of the foundations of SNA and the basic concepts and measures used in applying the method. More advanced concepts and measures exist such as small worlds, preferential attachment, core-periphery structures, and estimated random graph models. Such advanced concepts and measures are deserving of attention,

but fall outside the scope and space of this article. We also covered a variety of examples of applications of SNA across applied social and behavioral science fields. These examples are certainly not exhaustive, but indicative of how SNA measures for node-level analysis, network-level analysis, and flow analysis can be used. In presenting this overview and these examples we have demonstrated both the conceptual and empirical import of SNA for addressing relational issues and phenomena in applied social and behavioral sciences.

The potential for applying SNA is vast, but not without challenges. The collection of social network data can be problematic, particularly when complete data on a network are needed to have a proper understanding of network structure. Once such challenges are overcome, SNA can be: employed to understand and progress communications in organizations, workgroups, schools, and health care systems; used to analyze and improve the dissemination of research findings and products by researchers and research initiatives; applied to investigate and find weaknesses in criminal and terrorist networks; utilized to evaluate the collaborations fostered by a new grant program or research initiative; and can be used to study the spread of communicable diseases. All of these examples are issues of a relational nature and as such require SNA to be addressed. The concepts, measures, and examples laid out in this article demonstrate how to begin to do so.

Abstract

Recent developments in statistical models for social networks reflect an increasing theoretical focus in the social and behavioral sciences on the interdependence of social actors in dynamic, network-based social settings. As a result, a growing importance has been accorded the problem of modeling the dynamic and complex interdependencies among network ties and the actions of the individuals whom they link. The early focus of statistical network modeling on the mathematical and statistical properties of Bernoulli and dyad-independent random graph distributions is reviewed. These early efforts have now been replaced by distributions that consist of theoretically and empirically plausible parametric models for structural network phenomena. These new models, discussed in detail here, allow complicated dependencies among the network ties, and have many possible special cases, reflecting the complexity of the social network paradigm.

Late twentieth-century developments in statistical models for social networks reflect an increasing theoretical focus in the social and behavioral sciences on the interdependence of social actors in dynamic, network-based social settings. As a result, a growing importance has been accorded the problem of modeling the dynamic and complex interdependencies among network ties and the actions of the individuals whom they link. The early focus of statistical network modeling on the mathematical and statistical properties of Bernoulli and dyad-independent random graph distributions has been replaced by efforts to construct theoretically and empirically plausible parametric models for structural network phenomena and their changes over time. These models in this article are based on graphs where the nodes are individual actors, which are 'linked' by lines representing relational ties (*see* Graphical Markov Models: Overview).

Statistical Models for Social Networks

Notation

In most of the literature on statistical models for networks, the set $N = \{1, 2,\ldots, n\}$ of network nodes is regarded as fixed and the edges, or ties, between nodes are assumed to be random. The tie linking node i to node j ($i, j \in N$) may be denoted by the random variable X_{ij}. In the simplest case of binary-valued random variables, X_{ij} takes the value 1 if the tie is present and 0 otherwise. Other cases of interest include:

1. valued networks where X_{ij} is assumed to take values in the set $\{0, 1,\ldots, C-1\}$;
2. multiple relational or multivariate networks, where the variable X_{ijk} represents the possible tie of type k from node i to node j (with $k \in R = \{1,2,\ldots, r\}$, a fixed set of types of tie); and
3. time-dependent networks, where X_{ijt} represents the tie from node i to node j at time t.

In each case, network ties may be *directed* (e.g., X_{ij} and X_{ji} are distinct random variables) or *nondirected* (e.g., X_{ij} and X_{ji} are not distinguished). The $n \times n$ array $\boldsymbol{X} = [X_{ij}]$ of random variables can be regarded as the adjacency matrix of a random (directed) graph on N; the state space of all possible realizations of these arrays may be denoted by Ω_n. The array $\boldsymbol{x} = [x_{ij}]$ denotes a realization of $\boldsymbol{X}$, with $x_{ij} = 1$ if there is an observed tie from node i to node j, and $x_{ij} = 0$ otherwise. In some cases, models may also refer to variables measured on actor attributes: for instance, the mth attribute $Z_1^{[m]}$ of actor i gives rise to a random vector $\boldsymbol{Z}^{[m]}$ with realization $\boldsymbol{z}^{[m]}$.

The adjacency matrix of an illustrative nondirected binary network is shown in **Table 1**. The data are from a study of interorganizational networks amongst mental health agencies conducted by Morrisey et al. (1994). The nodes of the network are 37 mental health agencies in one of the US cities in the Morrissey study; an edge links two agencies if they engage in regular and mutual exchange of information. The graphical representation of these data is shown in **Figure 1**. We use this network to illustrate several of the distributions and models described below.

Bernoulli Graphs

A simple statistical model for a (directed) graph assumes a Bernoulli distribution, in which each edge, or tie, is statistically independent of all others and governed by a theoretical probability P_{ij}. In addition to edge independence, simplified versions also assume equal probabilities across ties; other versions allow the probabilities to depend on structural parameters (Frank and Nowicki, 1993). These distributions have often been used as models (Bollobas, 1985), but are of questionable utility due to the independence assumption. Bernoulli graph distributions are described at length by Erdos and Renyi (1960) and Frank (1981).

Dyadic Structure in Networks

Statistical models for social network phenomena have been developed from their edge-independent beginnings in a number of major ways. In one important series of

developments, the p_1 model introduced by Holland and Leinhardt (1981), and developed by Fienberg and Wasserman (1981), recognized the theoretical and empirical importance of dyadic structure in social networks, that is, of the interdependence of the variables X_{ij} and X_{ji}. This class of Bernoulli dyad distributions and their generalization to valued, multivariate, and time-dependent forms, gave parametric expression to ideas of reciprocity and exchange in dyads and their development over time. The model assumes that each dyad (X_{ij}, X_{ji}) is independent of every other and, in a commonly constrained form, specifies:

$$P(X=x)=\prod_{i<j}\exp\left\{\lambda_{ij}+\theta\left(\sum_{i\neq j}x_{ij}\right)+\rho\left(\sum_{i<j}x_{ij}x_{ji}\right)+\alpha_i\left(\sum_{j}x_{ij}\right)+\beta_j\left(\sum_{i}x_{ij}\right)\right\} \quad [1]$$

where θ is a density parameter; ρ is a reciprocity parameter; the parameters α_i and β reflect individual differences in expansiveness and popularity; and λ_{ij} ensures that probabilities for each dyad sum to 1. This model is log-linear (*see* Multivariate Analysis: Discrete Variables (Loglinear Models)).

An important elaboration of the p_1 model permits the dependence of density, popularity and expansiveness parameters on a partition of the nodes into subsets that can either be specified *a priori* (e.g., from hypotheses about social position) or can be identified *a posteriori* from observed patterns of node interrelationships (e.g., Wasserman and Faust, 1994). The resulting stochastic blockmodels represent hypotheses about the interdependence of social positions and the patterning of network ties (as originally elaborated in the notion of blockmodel by White et al., 1976). A potentially valuable variant of these models regards the allocation of nodes to blocks as a latent classification; Snijders and Nowicki (1997) have provided Bayesian estimation methods for the case of two latent classes. Another valuable extension of the p_1 model is the so-called p_2 model (Lazega and van Duijn, 1997). Like the p_1 model, the p_2 model assumes dyad independence, but it adds the possibility of arbitrary node and dyad covariates for the parameters of the p_1 model, and models the unexplained parts of the popularity and expansiveness parameters as random rather than fixed effects.

Null Models for Networks

Despite the useful parameterization of dyadic effects associated with the p_1 model and its generalizations, the assumption of dyadic independence has attracted sustained criticism. Thus, another series of developments has been motivated by the problem of assessing the degree and nature of departures from simple structural assumptions like dyadic independence. Following a general approach exemplified by early work of Rapoport (e.g., Rapoport, 1949), a number of conditional uniform random graph distributions were introduced as null models for exploring the structural features of social networks (see Wasserman and Faust, 1994 for a historical account). These distributions, denoted by $U|Q$, are defined over subsets Q of the state space Ω_n of directed graphs, and assign equal probability to each member of Q. The subset Q is usually chosen to have some specified set of properties (e.g., a fixed number of mutual, asymmetric, and null dyads, as in the $U|MAN$ distribution of Holland and Leinhardt, 1975). When Q is equal to Ω_n the distribution is referred to as the uniform (di)graph distribution, and is equivalent to a Bernoulli distribution with homogeneous tie probabilities. Enumeration of the members of Q and simulation of $U|Q$ is often straightforward (e.g., see Wasserman and Pattison, 2002), although certain cases, such as the distribution that is conditional on the indegree $(\sum_j x_{ji})$ and outdegreee $(\sum_j x_{ij})$, of each node i in the network, require more complicated approaches (Snijders, 1991; Wasserman, 1977).

A typical application of these distributions is to assess whether the occurrence of certain higher-order (e.g., triadic) features in an observed network is unusual, given the assumption that the data arose from a uniform distribution that is conditional on plausible lower-order (e.g., dyadic) features (e.g., Holland and Leinhardt, 1975). For example, the network displayed in **Table 1** has 84 edges, and 333 and 69 triads with exactly 2 and 3 edges, respectively. If Q denotes the subset of complete Ω_{37} with 84 edges, the expected number of triads of each kind is 250.1 and 50.8, and the observed values lie at the 0.003 and 0.005 percentiles of the $u|x_{++} = 84$ distribution,

Figure 1 Graphical representation of interorganizational networks amongst mental health agencies in one US city (data from Morrisey, J.P., Calloway, M., 1994. Local mental health authorities and service system change: Evidence from the Robert Wood Johnson Foundation Program on chronic mental illness. The Milbank Quarterly 72 (1), 49–80.).

respectively. This general approach has also been developed for the analysis of multivariate social networks. The best-known example of this approach is probably the quadratic assignment procedure or model (*QAP*) for networks (Hubert and Baker, 1978). In this case, the association between two graphs defined on the same set of nodes is assessed using a uniform multivariate graph distribution that is conditional on the unlabelled graph structure of each univariate graph. In a more general framework for the evaluation of structural properties in multivariate graphs, Pattison et al. (2001) also introduced various multigraph distributions associated with stochastic blockmodel hypotheses.

Extra-Dyadic Local Structure in Networks

A significant step in the development of parametric statistical models for social networks was taken by Frank and Strauss (1986) with the introduction of the class of Markov random graphs. This class of models permitted the parameterization of extra-dyadic local structural forms and so allowed a more explicit link between some important network conceptualizations and statistical network models. Frank and Strauss (1986) adapted research originally developed for modeling spatial dependencies (*see* Spatial Statistical Methods) among observations to graphs. They observed that the Hammersley-Clifford theorem provides a general probability distribution for $\boldsymbol{X}$ from a specification of which pairs (X_{ij}, X_{kl}) of edge random variables are conditionally dependent, given the values of all other random variables (*see* Graphical Markov Models: Overview).

Define a dependence graph $\mathbf{D}$ with node set $N(D) = \{(X_{ij} : i, j \in N, i \neq j\}$ and edge set $E(\mathbf{D}) = \{(X_{ij}, X_{kl})$: X_{ij} and X_{kl} are assumed to be conditionally dependent, given the rest of $\boldsymbol{X}\}$. Frank and Strauss used $\mathbf{D}$ to obtain a model for $\Pr(\boldsymbol{X} = \boldsymbol{x})$, denoted p^* by Wasserman and Pattison (1996), in terms of parameters and substructures corresponding to cliques of $\mathbf{D}$. The model has the form

$$\Pr(X = x) = p * (x) = (1/c)\exp\left\{\sum_{P \subset N(D)} \alpha_P Z_P(x\}\right\} \qquad [2]$$

where:

a. the summation is over all cliques P of $\mathbf{D}$ (with a clique of $\mathbf{D}$ defined as a nonempty subset P of $N(\mathbf{D})$ such that $|P| = 1$ or $(X_{ij}, X_{kl}) \in E(\mathbf{D})$ for all $X_{ij}, X_{kl} \in P$);

b. $Z_p(x) = \prod_{x_{ij} \in p}^{x_{ij}} x_{ij}$ is the (observed) network statistic corresponding to the clique ρ of $\mathbf{D}$; and

c. $c = \sum_x \exp\{\sum_p \alpha_p z_p(\boldsymbol{x})$ is a normalizing quantity.

specification of a dependence graph raises a deep theoretical issue for network analysis: what constitutes an appropriate set of dependence assumptions? Frank and Strauss (1986) proposed a Markov assumption, in which $(X_{ij}, X_{kl}) \in E(\mathbf{D})$ whenever $\{i, j\} \cap \{k, l\} \neq \varphi$. This assumption implies that the occurrence of a network tie from one node to another is conditionally dependent on the presence or absence of other ties in a local neighborhood of the tie. A Markovian local neighborhood for X_{ij} comprises all possible ties involving i and/or j. Any network tie is seen both as dependent on its neighboring ties and as participating in the neighborhood of

other ties, so the resulting model embodies the assumption that social networks have a local self-organizing quality. In the case of Markovian neighborhoods, cliques in the dependence graph correspond to triadic and star-like network configurations. A homogeneity assumption, that model parameters do not depend on the specific identities of nodes but only on the network configurations to which they correspond, yields a model that expresses the probability of the network in terms of propensities for subgraphs of triadic and star-like structures to occur.

For example, a homogeneous Markov model for the network of **Table 1** with parameters corresponding to edges, 2-stars, and triangles appears to be a substantial improvement in fit over a Bernoulli model with just an edge parameter, since the mean absolute residual for fitted edge probabilities drops from .220 to .175. Pseudolikelihood estimates for model parameters (Wasserman and Pattison, 1996) are −3.31, 0.056, and 0.616 for edges, 2-stars, and triangles, respectively, suggesting that graphs with a large number of triangles are relatively more likely in the assumed homogeneous Markov p^* distribution than those with few.

p^* random graph models permit the parameterization of many important ideas about local structure in univariate social networks, including transitivity, local clustering, degree variability, and centralization. Valued (Robins et al., 1999) and multivariate (Pattison and Wasserman, 1999) generalizations also lead to parameterizations of substantively interesting multirelational concepts, such as those associated with balance and clusterability, generalized transitivity and exchange, and the strength of weak ties.

Prospects for Structural Models

The p^* family of random graph models poses many interesting questions, both substantive and statistical. A major empirical question is the sufficiency of these local structural descriptions: do they suffice, or do they need to accommodate other characterizations of local dependence, more global considerations, other types of constraints (e.g., temporal and spatial), or variability in local structural dependencies? On the statistical side, major questions are raised by the complexity and rich parameterization of models that are deemed to be theoretically plausible. For instance, does a Markov chain Monte Carlo (*see* Markov Chain Monte Carlo Methods) maximum likelihood approach to parameter estimation offer a viable alternative to approximate methods such as pseudolikelihood estimation (Strauss and Ikeda, 1990)? How can these distributions best be simulated, and what are the convergence properties of various approaches, such as the Metropolis-Hastings algorithm?

Dynamic Models

Empirically and theoretically defensible parametric models for networks constitute one challenge for statistical modeling, but an arguably more significant challenge is to develop models for the emergence of network phenomena, including the evolution of networks and the unfolding of individual actions (e.g., voting, attitude change, decision-making) and interpersonal transactions (e.g., patterns of communication or interpersonal exchange) in the context of longer-standing relational ties. Early attempts to model the evolution of networks in either discrete or continuous time assumed dyad independence and Markov processes in time.

A step towards continuous time Markov chain models for network evolution that relaxes the assumption of dyad independence has been taken by Snijders (1996). These models incorporate both random change and change arising from individuals' attempts to optimize features of their local network environment (such as the extent to which reciprocity and balance prevail) and use the computer package *SIENA* for fitting. A tension function is proposed to represent the function that actors wish to minimize and Robbins-Munro procedures are used to estimate free parameters. The approach illustrates the potentially valuable role of simulation techniques for models that make empirically plausible assumptions; clearly, such methods provide a promising focus for future development.

The value of simulation has also been demonstrated by Watts and Strogatz (1998) and Watts (1999) in their analysis of the so-called small-world phenomenon (the tendency for individuals to be linked by short acquaintanceship network paths). They considered a probabilistic model for network change in which the probability of a new tie was determined, in part, by existing patterns of neighboring ties (a clustering component) and, in part, by a small random component. They used simulations to establish that only a small random component was needed for the simulated network to be likely to possess the small-world property.

Models Bridging Analytic Levels

A recurring theme among social theorists is the need for models that integrate the dynamic, interdependent, interpersonal, and cultural contexts in which social action occurs. The network modeling challenge posed by such framing of the nature of social processes is the development of models that represent interdependencies across several analytic categories (e.g., individuals, relational ties, settings, groups).

Snijder's (1996) model for network change represents one step in this direction; the class of social influence models represents another (Friedkin, 1998). These models are exemplified by the network effect model for the mth attribute variable:

$$Z^{[m]} = \alpha x z^{[m]} + \gamma\beta + \varepsilon \tag{3}$$

where α is a network effects parameter, γ is a matrix of exogenous attribute variables with corresponding parameter vector β, and ε is a vector of residuals.

A further step in the direction of modeling interdependent node attributes and network ties has been to generalize the dependence graph approach to p^* network models (Section Extra-dyadic Local Structure in Networks) so as to include both node attribute variables ($Z^{[m]}$) and relational variables (X). This step is facilitated if directed dependencies are permitted in the dependence graph (i.e., dependencies in which one random variable is assumed to be conditionally dependent on a second, but the second not on the first). Robins et al. (2001) drew on graphical modeling techniques to construct models with directed dependencies among

network ties and individual attributes. If the dependencies are directed from network ties to node attributes, models for social influence are obtained; with dependencies oriented from node attributes to network ties, social selection models result. Indeed, this generalization introduces substantial flexibility in model construction, with potential applications to joint influence and selection models, discrete time models for network change, network path models, and group-level attribute models.

The dependence approach of Section Extra-dyadic Local Structure in Networks has also been used to construct principled models for more general multiway relational data structures representing interdependent analytic categories. Examples to date have included bipartite (Faust and Skvoretz, 1999) and *k*-partite (Pattison et al., 1998) graphs and illustrate how this general distribution has the capacity for a systematic and coherent approach to a variety of major network modeling challenges.

Conclusion

In addition to some of the specific future prospects already noted, a more general expectation is that the current classes of models are likely to be the foundation of substantial empirical and model-building activity in the early twenty-first century. From their early beginnings, statistical approaches to network modeling have now reached a point where sustained interaction is likely to be empirical research that allows the development of greatly improved models for processes occurring on networks, with important applications in many fields of social and behavioral science, including epidemiology, organizational studies, social psychology, and politics.

For more information on these approaches to social networks analysis, please see Wasserman and Faust (1994) and Wasserman and Pattison (1996, 2002).

Abstract

This article reviews key ideas in social network analysis methods. Key concepts for describing the connections of individuals and groups into networks of social relations are introduced and defined. The article identifies the terminology of points and lines for understanding sociograms and reviews concepts of adjacency, degree, centrality, and forms of cohesion and subrouping. Developments in statistical methodology of hypothesis testing are examined and views of the evolution of social networks over time are considered. It is argued that social network analysis is to be considered as a methodological approach rather than a substantive body of theory, although it is shown that there are close links between social networks analysis and theories of social structure and social capital. It is argued that social network analysis is an essential adjunct to any approach to relational sociology.

Social network analysis is the study of the patterns of social relations that comprise social structures, treating these relations as networks of connections among the individuals and groups that enter into them. While these relations may be formed by particular individuals, social network analysis is not limited to microlevel interactions. Individuals form social relations as the occupants of institutionally defined positions in social organizations, and the social relations enter into the constitution of patterns of macrolevel relations that may equally be treated as social networks. A large number of concepts have been developed to characterize, measure, and compare network structures and positions in networks. These include the relative centrality of individuals, groups, and positions within networks; their clustering into subgroups; the overall cohesion or density of a network; and the centralization of networks around focal points. A number of statistical methods have been developed to estimate their values and to assess the significance of these measures for observed outcomes.

There are a number of introductions and overviews of social network analysis. A nontechnical introduction is Scott (2013), and there are a number of introductory surveys (Degenne and Forsé, 1994; Knoke and Song, 2008; Prell, 2012; Kadushin, 2012; Scott, 2012). The best advanced text is that of Wasserman and Faust (1994). A comprehensive collection of discussions and applications has been brought together by Carrington and Scott (Carrington and Scott, 2011).

Concepts and Techniques of Network Analysis

In social network analysis, social structures are represented as patterns of points (or vertices) and lines (or edges). The points represent individuals, organizations, or positions, while the lines represent the relations that connect them. Any type of dyadic relationship can be represented, including communication, friendship choices, advice, trust, influence, and exchange relationships. The lines depicting the relationship can be characterized by various attributes. Relations may first be described as directed or undirected. A line can be said to be directed from one point to another, for example, when one person chooses another as a friend but this choice is not reciprocated. The direction assigned to the line represents the likely flow of information or resources between the two participants. These directed lines are often termed 'arcs.' Undirected lines are those that represent reciprocated links or common memberships, as in the case of two people who meet as members of the same group or through participation at the same event. Lines can also be distinguished by signs attached to them to indicate the type of relationship. Positive or negative signs on directed lines, for example, enable the representation of positive and negative relations such as cooperation and conflict. The strength of a relation may be represented by a number, either an actual number (such as the size of a shareholding) or a scaled representation of strength. Such lines are said to be 'valued.'

This language of points and lines, with directions, signs, and values, provides an intuitive form of representation that can help in the drawing of simple sociograms. The sociogram, largely invented by Jacob Moreno (1934), is a simple visual mapping of the pattern of connections and is most easily used in the study of small groups. Indeed, the area of group dynamics (Cartwright and Zander, 1953) largely developed as a reflection on the consequences of different communication patterns in small groups. An example of this kind of work might be Heider's development of balance theory to study social influence within groups. Heider represented cognitive balance as a signed graph with three points. An individual under study can have a positive or negative relationship to another person. Both persons can have a positive or negative attitude toward another object (e.g., a third person or a certain activity). The cognitive system of the individual under study is in balance if and only if all three relationships are positive or two of them are negative. Harary et al. (1965) generalized the idea of balance to a whole social system.

Developments beyond simple representations in sociograms have involved the use of matrix algebra and graph theory (see particularly Harary et al., 1965). Major computational possibilities became possible by the representation of a social network in a matrix. The rows and columns represent the points, and the cells the relationships from the row to the column point. In an adjacency matrix, only ones (for a directed line from the row point to the column point) or

zeros (no such line) are used. In a signed graph, positive ties are represented by +1 and negative ones by −1. In a valued graph, the values of the ties can be given. Graphs with different types of relationships (denoted multigraphs) can be represented by stacked matrices. Graph theory is a branch of formal mathematics that has been used in the modeling of networks – or 'graphs' – in such diverse areas as electrical networks, computer networks, and networks of rivers. The use of graph theory allows the formal properties of large networks to be explored and summarized in numerical form. The basic concepts used to describe a pattern of points and lines in graph theory are adjacency, neighborhood, and distance, and these can be used to describe more complex relational structures (Bonacich and Lu, 2012).

Adjacency refers to the simple fact of connection: two connected points are said to be adjacent to each other. The 'degree' of a point is the number of other points to which it is adjacent, and the neighborhood of a point comprises the set of other points to which it is adjacent. When account is taken of the direction assigned to a line, it is possible to distinguish the 'indegree' and the 'outdegree' of a point and so to differentiate its neighborhood. Points in a network are connected by 'paths' – sequences of lines – of varying length, the number of lines in a path. The length of the shortest path indicates the distance between two points. Adjacent points are connected by a path comprising a single line and are said to be connected at a distance of one. Indirect links through, for example, a common friend are at a distance of two, and so on. The famous research of Stanley Milgram (1967) showed the significance of six degrees of separation: the fact that randomly chosen people, even if located in different continents, are typically connected to each other through intermediaries by a path of maximally length six.

These basic concepts allow the construction of measures of the relative centrality of points within a network. Freeman (1978) associated the many centrality measures with three important centrality dimensions in communication networks. These are local centrality, global centrality, and betweenness. Local centrality is measured by the degree, the number of points with which a point is directly connected, which is assumed to indicate the communication activity of a point. It is a measure of how well connected a point is in its local environment. In directed networks, centrality in terms of outdegree and indegree should usually be distinguished. In friendship choice networks, for example, the number of choices received (indegree) generally indicates centrality, which may be seen as a measure of likability. In influence networks, local centrality may be based on the number of outgoing relationships (outdegree). When the overall network is considered, rather than its local structure, one is dealing with global centrality. This involves the use of distance-based measures to indicate the relative proximity of points to other points in the network and the extent to which a point can communicate with other points independently of others. In the literature, various statistical measures on the distances of a point to other points are used to measure this dimension of centrality, such as the mean distance to other points or the maximal distance to any of the other points. Betweenness, or rush, is the third type of centrality and measures how important a point is for the transmission of information between other points. Betweenness measures assume that information is mainly transmitted through the shortest paths. A point with a high betweenness might be regarded as a key 'broker' or intermediary in a network.

The measures considered so far can all be considered to be attributes of particular points within a network, based on their relations with others. They are often referred to as measures for 'egonets.' However, it is also possible to consider the global structure of the network itself and to characterize its overall pattern. The most important are density, centralization, and clustering. Density is the number of distance-one relationships that actually exist relative to the total number that might possibly exist. It measures how 'complete' a web of connections may be. Dense networks are more important for control and sanctioning than for information. They also tend to generate a lot of redundant information and so result in many constraints and are inefficient for creative new solutions (Burt, 1992). Comparing densities of networks of quite different sizes is difficult, as large networks tend to be sparse and the measure of density varies directly with the typical neighborhood size (which increases much more slowly than the size of the whole network). The centralization of a network is a measure of the extent to which its connections coalesce around a small subset of globally central points. In connected networks, high centralization corresponds with a high variance of the degrees of the points. Snijders (1981) derived the maximal possible values of the variance, given the number of points or the number of points and lines. He also derived the expected variance for different null models under the same two conditions. This makes a good comparison of centralization possible in networks of different sizes and densities. The third global measure is the clustering or segmentation of the network. A simple summary measure of segmentation is the number of pairs of points at distance two or higher divided by the number of pairs of points at distance three or higher (Baerveldt and Snijders, 1994). More structural measures, however, employ forms of cluster analysis and subdivision to identify clusters, cliques, and components within a network. Such measures of the social circles within which individuals and groups interact provide a picture of the overall shape or landscape of a network. Structurally equivalent points do not have the same connections, but they do have the same types of connections. This kind of analysis has been seen as identifying typical roles or positions within networks.

A large number of other network studies examine the effects of the network structure on the behavior and attributes of the network members. In these studies, the network is considered as given and constant, and the ways in which this network influences processes or individuals in the network is examined. In many of these studies, only relationships of the individuals under investigation are collected (at most combined with their perception of the relationships among their network members). These ego-centered network studies examine the effects of differences in size and composition of the personal networks and the multiplexity of an individual's personal relations (Wellman and Berkowitz, 1997). Examples of effects studied are an individual's social well-being, social support, health, labor market position, and career.

Many of the central properties of social networks studied by graph theory have been shown to depend on what have been

called small-world conditions (Watts, 1999, 2003). That is, they apply when the pattern of connections is such that Milgram's suggestion of six degrees of separation holds. Fundamentally different processes will be in operation in networks where the number of connections is so low that this does not happen or where the connections are so high that almost all individuals are closely connected. Thus, a network that changes incrementally may reach a point at which the pattern of connections changes catastrophically and with radical consequences for the members of the network.

The bulk of the measures in social network analysis are based on so-called one-mode data. That is, when individuals are related to each other by common organizational membership, analysis has focused on either the individuals or the organizations. Recent developments have undertaken systematic simultaneous analyses of both individuals and organizations, representing them all as points within the same network. Measures of centrality, for example, are difficult to conceptualize and understand for two-mode data, but much work is progressing to clarify this. An early usage of two-mode data was block modeling, in which both sets of points were simultaneously partitioned into subsets that could be treated as 'equivalent' to each other (Everett and Borgatti, 1994).

An important area of development in social network analysis has been the use of multidimensional scaling, principal components analysis, and similar techniques to present graphical visualizations of social networks. These techniques allow a more rigorous extension of the principle of the sociogram and embed images of social networks in a multidimensional space in which distances and directions are depicted as they would be in a geographical map. Thus, distance in this social space differs from the path distance of graph theory as it takes account of the relative closeness of all points within the network. These developments have led to an impressive range of visualization techniques, many of which are accessible through the Pajek software (de Nooy et al., 2005). General network concepts can be usefully explored through the UCINET software developed by Freeman, Borgatti, and Everett (http://www.analytictech.com/).

Statistical Models for Social Network Analysis

Much research in social network analysis has been descriptive and has prompted questions about the significance of the structures described for actual behavioral outcomes. Recent developments have produced a range of statistical techniques that can allow the use of social network analysis in explanatory studies by assessing the statistical significance of the results.

Standard statistical models are more difficult to apply to social networks because the relationships between the points cannot be treated as independent observations. The most useful alternative to have been developed involves exponential random graph models in which observed patterns are compared with those found in large numbers of random computer simulations given certain characteristics of the overall network to assess the probability that the observations are the result of chance (Wasserman and Pattison, 1996; Snijders et al., 2006; Robins et al., 2007).

Evolution and Network Dynamics

Along with the move from descriptive to explanatory concerns, there has been a move from static to dynamic analyses. Existing concepts have been largely concerned with the static, cross-sectional features of social networks and fail to grasp the complexities of social change. Recent work has taken more seriously the fact that social networks change over time and that these patterns and processes of change must be explained. Like all social structures, social networks are produced and reproduced through individual and collective action, but their structures are generally the unanticipated and unintended consequences of these actions. Agent-based computational models of action (Axelrod, 1997) have been particularly useful in understanding this process and in allowing connections to be made with Markov models of stochastic change.

Holland and Leinhardt (1977) introduced Markov processes as the general framework for stochastic models of network evolution. The basic idea of Markov models is to conceive the social network structure as changing from one state into another over time. The parameters that govern the process concern the likelihood of transition from one of these four states into another. The original Markov models assume that the parameters are stationary over the whole process and that the population is homogeneous. Recent models have considerably increased the analytic possibilities of Markov models by eliminating these strongly limiting assumptions and recognizing that change parameters may well be dependent on the stage of network development and will be different for pairs within and between subgroups (Leenders, 1996). Snijders powerfully integrated Markov models with random utility models to allow a much stronger link between theory and statistical testing (Snijders, 1996), where actors are seen as making and breaking links on the basis of local knowledge and decision rules that generate unplanned but structured long-term changes. Many of the general issues in this area are considered in Doreian and Stokman (1997).

One of the most important theoretical topics in social network analysis concerns the relative importance of selection and influence processes: do, for example, friends seek and select friends with similar characteristics or become friends more similar because of their repeated interactions? As both networks and characteristics like attitudes change over time, the relative importance of the two processes is one of the key questions social networks researchers seek to answer. Snijders' dynamic approach to network analysis (Snijders, 2011) makes it possible to estimate the relative importance of the two processes in designs where we have data at three or more time points.

Method or Theory?

Social network analysis is primarily to be understood as a method of analysis and not as a substantive theoretical approach. It is, however, more compatible with certain theoretical approaches and can be considered as an essential adjunct of any relational sociology (Emirbayer, 1997). Early

arguments emphasized the links between social network analysis and exchange theory.

The fact that social networks create conditions for cooperation through information and sanctioning is due to exchange processes that create win–win situations (Homans, 1950; Blau, 1964). A fruitful and very promising approach is the study of the effects of social networks in noncooperative game theory (Raub and Weesie, 1990; Flache and Macy, 1996; Bienenstock and Bonacich, 1992). Network exchange theory specifically investigates the effects of network structures on the choice between alternative exchanges and on exchange rates (Willer, 1999). Major effects are particularly due to possibilities for social actors to exclude others. Exchange network theory illustrates again that effects of network structures are context sensitive and cannot be generalized without taking the context and substance into account. The integration of exchange theory and social networks has also been proved to be very successful in the field of policy networks. Most of these models build on Coleman's social exchange model and confine exchanges to influence network relationships (Laumann et al., 1987). These models make the step from microbehavior to macroeffects explicit and are able to predict outcomes of decisions, to derive the power of social actors and the value of decisions. Later models try to solve a number of remaining theoretical issues (Stokman and Van den Bos, 1992; Pappi and Henning, 1998). Stokman et al. (2013) give a more general theory of bargaining in which three fundamental bargaining processes (persuasion, logrolling, and enforcement) are related to three types of social networks (information, exchange, and hierarchical power networks). They argue that in any bargaining situation all three are present, but only one is likely to be dominant.

Social network analysis has recently, however, been shown to be especially fruitful for discussions of social capital. Social capital gives individuals access to resources of others that can be exploited for the realization of their goals and so constitutes an opportunity structure generated by social relationships (Lin, 1982; Coleman, 1990; Burt, 1992). The amount of social capital depends on the amount of these resources, their value for the goal realization of the individual, and the willingness of others to mobilize them (Flap, 1999). The value of the resources for the individual strongly depends on functional interdependence, the willingness of others to mobilize resources for the individual on their perception of the interdependence (i.e., the cognitive dependence). Social capital emphasizes the relationship between social capital and success of actors, whereas Lindenberg and Foss (2011) change the perspective to success of group production and derive the conditions for joint production motivation. Important ideas developed by Putnam (2000) on bridging and bonding capital can be directly modeled in network terms. Large and dense networks create shared information, high visibility, and common norms in a community. Burt (1992), on the other hand, stresses the importance of unique and nonoverlapping relationships for acquiring unique information in organizations, giving individuals a better chance to find creative solutions for problems and thus providing them better opportunities for career. Vedres and Stark (2010) disputed Burt's emphasis on broker positions for performance and introduced the concept of structural folds, where success is related to overlapping memberships in different groups rather than isolated positions between groups.

Functional and cognitive interdependencies differ particularly between what Granovetter (1973) has termed strong and weak ties. Strong ties are valued in themselves. The ties are not primarily instrumental for the attainment of other goals. Their value is based on the other individual as a person and the quality of the relationship with that individual. Family and friendship ties are typical examples of such relationships. Strong ties tend to be reciprocal, transitive, and clustered. Strong ties give a sense of belonging to a group and the group often has priority above the individual and individual relationships. Sharing is often based on need and norms tend to promote equality (Lindenberg, 1998). Creating negative attitudes toward other groups often helps to strengthen the predominance of the group, which may give strong negative externalities for society as a whole (think of gangs and other criminal organizations). Weak ties are valuable long-term relationships but their value is primarily instrumental, related to higher ordered goals, goals not primarily located in the relationship or individuals themselves. Weak ties tend to be less clustered; the group is less dominant and often only vaguely delineated. Reciprocity based on equity norms prevails.

Conclusion

Since the early 1970s, there has been impressive cumulative progress in social network analysis and research. From a rather isolated field, strongly oriented to descriptive structural and static analysis, social network analysis has grown into a well-embedded field, widely accepted as highly important for solving central theoretical problems of cooperation and coordination. With the growing importance of social networks in the information society with virtual communities developing in many segments of society, its importance and contributions to theoretical solutions can only grow. Issues of scope are challenging. Objects of study will vary from small group networks to social networks of billions of points. New techniques to visualize networks are also challenging. These allow certain structural characteristics to become visible and the effects of changes on these characteristics to become transparent. These developments can be followed by linking with the international virtual community of the International Network for Social Network Analysis and the links to be found there (http://www.insna.org/).

Abstract

We summarize algebraic representations for multiple social networks and review recent steps that have been taken to extend these representations to the case of dynamic multiple networks. The primary purpose of these algebraic constructions is to establish the foundations for some useful computations in multiple networks and to develop the basis for structural analysis and comparison of multiple network structures.

Introduction

Since social networks are fundamentally relational structures, it is not surprising that algebraic approaches to understanding relational structure have been explored in the context of social networks (for example, Bonacich and McConaghy, 1979; Boorman and White, 1976; Boyd, 1989, 1990; Kim and Roush, 1984; Luce, 1956; Boyd et al., 1989; Lorrain, 1975; Lorrain and White, 1971; Pattison, 1993; see also Pattison, 2009, 2011; Pattison and Bartlett, 1982; White, 1963). In this article, we summarize algebraic representations for multiple social networks and review recent steps that have been taken to extend these representations to the case of dynamic multiple networks. As we describe below, the primary purposes of these algebraic constructions are as follows: first, to establish the foundations for some useful computations in multiple networks and, second, to develop the basis for structural analysis and comparison of multiple network structures.

We begin with a fixed primitive set of *relational types*, such as friendship, collaboration, acquaintanceship, and so on. Each relational type is taken to be associated with a *network* on a fixed set N of actors or nodes. The network can be represented interchangeably as a *binary relation* (a set of ordered pairs of elements of N), a *directed graph* (a set N of nodes and a set of directed edges, each of which is an ordered pair from N), or an *adjacency matrix* on the node set N (that is, a matrix whose (i,j) entry is 1 if and only if (i,j) is an element in the binary relation for the network or, equivalently, an edge in its directed graph). For a relation of type A, we write $a(i,j) = 1$ if i is connected to j in the network for the relation, and $a(i,j) = 0$, otherwise. In other words, we represent the relation of type A as an $n \times n$ matrix $a = [a(i,j)]$, and the entries of the matrix a have values from the set $\{0,1\}$. We refer to unit entries of $a(i,j)$ as *links*, or *ties*, in the network a.

In the case of some relationships, such as parenthood, the direction of the network connection between two nodes is a vital consideration, whereas in others it may be assumed to be unimportant as, for example, in relationships of collaboration. Where the directionality of network ties is assumed a priori not to matter, the network is defined to be symmetric; that is, $a(i,j) = a(j,i)$ for all pairs i, j of nodes in N.

For a given set $\{A_1, A_2, \ldots, A_r\}$ of relational types, the set of networks $\alpha = \{a_1, a_2, \ldots, a_r\}$ on N constitutes a *multiple social network* on N. Below, we refer to the network elements of α as *generator* networks. To illustrate the constructions presented here, we use the hypothetical small example of a multiple social network $\alpha = \{a,b\}$ presented in **Table 1**.

In the first part of this article, we focus on the algebraic structures to which labeled walks and their sums in a multiple social network gives rise. In the second part, we consider *dynamic multiple social networks*, in which the set $\{0,1\}$ of possible relational values of $a(i,j)$ is replaced by a set of time intervals over which the relation or tie from node i to node j is taken to exist. Our focus then turns to time-ordered labeled walks (Moody, 2002) and the algebraic structures to which such walks and their sums give rise.

The Algebraic Structure of a Multiple Social Network

It is possible to define a variety of algebraic structures from a multiple social network (Pattison, 2009, 2011). The variations arise, in part, through the choice of elements over which the algebra is defined and, in part, through choice of the *operations* on those elements. As far as the choice of elements is concerned, most approaches have treated the constituent networks in a multiple social network as a set of generator elements (e.g., Boorman and White, 1976; Boyd, 1969, 1990; Boyd et al., 1989; Luce, 1956; Pattison, 1993; White, 1963), though some have restricted attention to the immediate *local* neighborhood of a selected node in the network (Breiger and Pattison, 1986; Mandel, 1983; Pattison, 1989; Winship and Mandel, 1983; Wu, 1983). The choice of operations has focused primarily on the binary relations of relational composition, Boolean addition and intersection and the unary converse or closure operations (e.g., Pattison, 2011). A natural partial order on networks has often also been incorporated (e.g., Pattison, 1993). Here, we focus principally on relational composition and Boolean sums as operations of primary interest, and also on the natural partial order relation, as explained below.

Table 1 A small hypothetical multiple social network $\alpha = \{a,b\}$ on node set $N = \{1,2,3,4\}$

	a				b			
1	0	1	0	0	0	0	1	0
2	0	0	0	0	0	0	0	1
3	0	0	0	1	1	0	0	0
4	0	0	0	0	0	1	0	0

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43116-8

The binary operation of *relational composition* is defined for arbitrary networks A and B on a node set N as the network corresponding to the Boolean product of the arrays a and b:

$$ab(i,j) = \sum_k a(i,k)b(k,j)$$

Note that both addition and multiplication are Boolean in this expression. The matrix $ab = [ab(i,j)]$ is said to have type AB and describes the presence or absence of labeled walks of type AB among pairs of members of the node set. In general, a *labeled walk* of type $A_1A_2\cdots A_p$ from a node i to a node j is a sequence of nodes $i = k_0, k_1, \ldots, k_p = j$ in which each pair (k_{m-1}, k_m) of adjacent nodes in the sequence is an edge in the network a_m $(m = 1, 2, \ldots, p)$. The length of the walk is p. Labeled walks in a multiple social network are important because they describe indirect relations implied by the generator networks and serve as potential conduits for social processes. For instance, if A refers to friendship and B refers to collaboration, then labeled walks of type AB describe pairs (i,j) of actors for whom j is a collaborator of a friend of i. If the generator set of networks comprises a single network a of type A, then aa, $(aa)a$, and so on, indicate pairs of nodes that are linked by walks in the network a of length 2, 3, and so on.

The *(Boolean) sum* of two arbitrary networks A and B on the same node set N is defined pairwise; that is,

$$(a+b)(i,j) = a(i,j) + b(i,j)$$

The pair of actors (i,j) are linked by the network $a + b$ if and only if i is linked to j by the network a and/or the network b. We refer to the type of the network $a + b$ as $A + B$. If A and B refer to friendship and collaboration, for example, then two nodes are linked by a relation of type $A + B$ whenever they are linked by a friendship and/or a collaboration tie.

We can also define a *natural partial order* on networks: for any two networks a and b on the same node set N, define $a \leq b$ if and only if

$$a(i,j) \leq b(i,j) \quad \text{for all } i,j \in N$$

Definition 1

A binary relation $\leq$ on a set S is a *partial order* if it has the properties:

1. *reflexivity*: $a \leq a$ for all $a \in S$;
2. *transitivity*: for any $a, b, c \in S$, if $a \leq b$ and $b \leq c$, then $a \leq c$; and
3. *antisymmetry*: for any $a, b \in S$, if $a \leq b$ and $b \leq a$, then $a = b$.

The natural partial order on networks with the same node set N is clearly a partial order.

The operations of relational composition and Boolean addition and the natural partial order relation have some well-known algebraic properties that give rise to some well-described algebraic structures on networks.

Definition 2

A (finite) *semigroup* $(S, \circ)$ is a (finite) set S endowed with a binary operation satisfying:

1. *closure*: for all $a, b \in S$, $a \circ b \in S$; and
2. *associativity*: for all $a, b, c \in S$, $(a \circ b) \circ c = a \circ (b \circ c)$.

If, in addition, $(S, \circ)$ satisfies:

3. *identity*: there is an *identity element*, $e \in S$ satisfying, for all $a \in S$, $a \circ e = e \circ a = a$,

then $(S, \circ)$ is termed a *monoid*.

Definition 3

A *partially ordered* semigroup (monoid) is a semigroup (monoid) $(S, \circ)$ together with a partial order $\leq$ on S that satisfies

$$\textit{isotonicity}: \text{if } a \leq b \text{ and } c \leq d, \text{ then } a \circ c \leq b \circ d \quad \text{for any } a, b, c, d \in S$$

It can readily be shown that the set of all binary relations on a set N forms a monoid under relational composition. The identity element is the *identity network* defined by

$$e(i,j) = 1 \quad \text{if } i = j; e(i,j) = 0, \text{ otherwise.}$$

Definition 4

For a given set of networks $\alpha = \{a_1, a_2, \ldots, a_r\}$ on node set N, we can define the *closure* α^* of α under relational composition as the set α^* of networks satisfying

1. *closure*: for all $a, b \in \alpha^*$, $a \circ b \in \alpha^*$;
2. *inclusive of generators*: $\alpha \subseteq \alpha^*$; and
3. *minimal*: for any set β that also satisfies closure and includes the generator set (that is, $\alpha \subseteq \beta$), then $\alpha^* \subseteq \beta$.

For any set of generator networks $\alpha = \{a_1, a_2, \ldots, a_r\}$ on N, α^* is a semigroup under relational composition, and $\alpha^* \cup e$ is a monoid (e.g., Boorman and White, 1976). Boorman and White referred to the semigroup α^* as the *role structure* on N generated by α, since it summarizes relationships of equality among all possible direct and indirect relations associated with the generator networks in α. It is worth emphasizing that implicit in the creation of α^* is the notion that any two networks in α^* are regarded as equal, if they link precisely the same pairs of actors in N. Boorman and White referred to this assumption as the *Axiom of Quality*, observing that it captures equations among direct and indirect relations on N. In other words, the semigroup α^* captures equations among all possible labeled walks that can be constructed from the generator networks $\{a_1, a_2, \ldots, a_r\}$.

Pattison (1993) argued that the partial order on networks in α^* also carries valuable information for analysis of the semigroup, and α^* and $\alpha^* \cup \{e\}$ are partially ordered semigroups and monoids, respectively, for any network generator set α.

In practice, the semigroup α^* of a multiple social network $\alpha = \{a_1, a_2, \ldots, a_r\}$ may be constructed as follows:

S1. Let $w_1 = \{a_1, a_2, \ldots, a_r\}$ and set $i = 1$.
S2. Construct the networks ab for each $a \in w_i$ and each $b \in w_1$. Place ab in the set w_{i+1} if $ab \neq c$, for any $c \in w_j$, $j = 1, 2, \ldots, i+1$; otherwise, $ab = c$ for some $c \in w_j$ $(j = 1, 2, \ldots, i+1)$ is an *equation* in the semigroup *on* α^*.
S3. If $w_{i+1} = \varnothing$, compute the partial order among networks in $w_1 \cup w_2 \cup \cdots \cup w_i$ and stop; otherwise, set i to $i+1$ and return to step S2.

The equations $ab = c$ may be recorded in a *right multiplication table* in which c appears as the table entry corresponding to the row labeled a and the column labeled b. If $n\alpha$ is the number of distinct networks in $\alpha^* = w_1 \cup w_2 \cup \cdots \cup w_i$, then the partial order can be written as an $n\alpha \times n\alpha$ matrix p in which $p(i,j) = 1$ if the jth element in α^* is less than the ith element in α^* and $p(i,j) = 0$, otherwise.

Definition 5

A *semiring* $(S,\circ,+)$ is a set S equipped with two binary operations $\circ$ and $+$ satisfying

1. $(S,\circ)$ is a monoid with identity e;
2. $(S,+)$ is a monoid with identity o;
3. *commutativity* of $+$: for all $a, b \in S$, $a + b = b + a$;
4. *distributivity* of $\circ$ over $+$: for all $a, b, c \in S$, $a\circ(b + c) = (a \circ b)+(a \circ c)$ and $(a + b)\circ c = (a \circ c)+(b \circ c)$; and
5. *absorption*: for all $a \in S$, $a \circ o = o \circ a = o$.

If $\leq$ is a partial order on S, then $(S,\circ,+,\leq)$ is a *partially ordered semiring* if, in addition,

6. *isotonicity* with respect to $\circ$: if $a \leq b$ and $c \leq d$, then $a \circ c \leq b \circ d$ for any $a, b, c, d \in$ S; and
7. *isotonicity* with respect to $+$: if $a \leq b$ and $c \leq d$, then $a + c \leq b + d$ for any $a, b, c, d \in$ S.

The set of all binary relations on a set N forms a partially ordered semiring, with relational composition and the Boolean sum taking the roles of the operations $\circ$ and $+$ and the natural partial order on networks on N. The identity element for the $+$ operation is the *null network* o defined by

$$o(i,j) = 0 \quad \text{for all } i,j \in N$$

We can also define the closure of the generator set α of networks under both relational composition and Boolean addition. In this case, the closure α^* is the minimal superset of α for which

1. *closure*: for all $a, b \in \alpha^*$, $a \circ b \in \alpha^*$, and $a + b \in \alpha^*$.

We will use α^* to refer to the closure of α, noting that it will be clear from the context over which operations closure applies.

The set of relations $\alpha^* \cup \{e,o\}$ closed under relational composition and Boolean addition and augmented by the identity and null networks form a semiring (e.g., Pattison, 2009). The semiring is partially ordered by the natural partial order on networks. The semiring may be constructed using a modified version of the algorithm above. The modification is to add an additional step between steps (S2) and (S3) of the algorithm above:

- compute $a + b$ for all $a \in w_j$, $j = 1,2,\ldots,i$; $b \in w_i$;
- place $a + b$ in w_{i+1} if $a + b \neq c$, for any $c \in w_j$, $j = 1,2,\ldots,i + 1$;
- otherwise, $a + b = c$ for some $c \in w_j$ $(j = 1,2,\ldots,i + 1)$ is an *equation* in the semiring.

In the special case where $\alpha = \{a\}$ comprises a single network generator, a number of mathematical results describe the relationship between network properties of a and algebraic properties of α^* (Kim, 1982; Pattison, 2009).

To illustrate these constructions, the multiple social network in **Table 1** gives rise to the partially ordered monoid whose distinct elements are listed in **Table 2** and whose right multiplication table and partial order are presented in **Table 3**. The same multiple social network gives rise to the partially ordered semiring with right multiplication table and partial order shown in **Table 4**. The addition table for the semiring is not shown but can be computed in a straightforward way using the Boolean addition operation on the elements of α^*.

Three primary applications have been made of these (partially ordered) semigroup, monoid, and semiring representations of multiple social networks in the literature on social network analysis.

The first is that many measures of interest in single and multiple social networks depend on walks in the network and hence formal algebraic representations of the type just defined establish the foundations for computation of those measures. It is well known, for example, that the *reachability* of node j from node i in a walk of length m or less in network a is captured by the (i,j) entry of the network $e \cup a \cup a^2 \cup \cdots \cup a^m$. Efficient algorithms for computation of walk-based measures can be developed given the underpinning algebraic properties (Brandes, 2001; Harary et al., 1965).

The second application takes advantage of the fact that these algebraic structures represent the relationships among labeled walks (and, in the case of semirings, their Boolean sums) in a way that does not depend directly on nodes and ties in the network constituents of α^*. As a result, structural comparisons across multiple social networks become possible, either through the identification of shared *homomorphic images* or shared sets of algebraic equations (Boorman and White, 1976; Bonacich, 1980; Bonacich and McConaghy, 1979; Boyd, 1969; Breiger and Pattison, 1978; McConaghy, 1981; Pattison, 1982, 1993).

Definition 6

If $\{a_1, a_2, \ldots, a_r\}$ and $\{a'_1, a'_2, \ldots, a'_r\}$ are two multiple social networks with a common set of relational types $\{A_1, A_2, \ldots, A_r\}$,

Table 2 Distinct elements in the monoid generated by the multiple social network $\alpha = \{a,b\}$ of **Table 1**

	a				b				o				ab				e

then the semigroup $(\alpha')^*$ is a *homomorphic image* of α^*, if there is a mapping φ from α^* to $(\alpha')^*$ such that

1. for each $b \in (\alpha')^*$, there is some $a \in \alpha^*$ such that $\varphi(a) = b$; and
2. $\varphi(ab) = \varphi(a)\varphi(b)$ for all $a, b \in \alpha^*$.

In this case, the mapping φ is said to be a *homomorphism*.

Interest is generally focused on those homomorphisms that are *generator-preserving*, that is, for which $\varphi(a_m) = a'_m$ for each generator a_m. If one semigroup is a (generator-preserving) homomorphic image of a second, it has the same structure as a partition of the second, and can therefore be seen as having a similar but 'coarser' structure than the first. Boorman and White (1976) advocated the use of the joint homomorphic image of the semigroups of two multiple social networks with the same generator types as a useful descriptor of shared structure, whereas Bonacich (1980) and Bonacich and McConaghy (1979) proposed the semigroup of the disjoint union of the two multiple social networks (for further discussion of the distinctive rationales of these two approaches, see Pattison, 1981).

A third application is to use structural analysis at the algebraic level to determine analysis at the network level, an approach pursued first by Boyd for group representations of kinship systems and later by others for more general semigroup representations of social networks (Bonacich, 1983; Boyd, 1969; Kim and Roush, 1984; Pattison and Bartlett, 1982; Pattison, 1982, 1993, 2009; White and Reitz, 1983). Structural analysis at the algebraic level generally entails identification of homomorphic image algebras in these approaches, and Pattison and Bartlett (1982; also Pattison, 1993) proposed analysis of an algebra into a set of maximally independent image algebras, termed *factors*. Pattison (1993) proposed a lattice-based algorithm for constructing the factors of a semigroup and an associated reduction of the underlying multiple social network. In many of these cases, use is also made of the natural partial order on α^*.

The Algebraic Structure of a Dynamic Multiple Social Network

The semigroup, monoid, and semiring representations described so far have entailed operations over networks in which ties take values from the set $\{0,1\}$, that is, in which ties are simply present or absent. In many social network applications of interest, however, network ties change over time. For example, two actors may be collaborators for a period of time, but then cease to collaborate; another two actors may have an antagonistic relationship, which later becomes friendship. Our second goal in this article is, therefore, to describe algebraic constructions for what we term *dynamic* multiple social networks. Following Kontoleon et al. (2013), we build on Moody's (2002) important insight that labeled walks of interest in dynamic multiple social networks must be *time-ordered* or *time-respecting* (see also Holme and Saramäki, 2011).

As for multiple social networks, we begin with a fixed primitive set of *relational types*, and a *network* associated with each relational type on a fixed set N of actors. Each network is now regarded as *dynamic* and the value of the tie $a(i,j)$ from actor i to actor j is a finite set of $n(a,i,j)$ strictly disjoint time intervals $\{[t_1,u_1], [t_2,u_2],\ldots, [t_{n(a,i,j)},u_{n(a,i,j)}]\}$ lying within some designated time period of interest, assumed without loss of generality, to be $[0,\omega]$. The time intervals $[t,u]$ are such that $t \leq u$, and if the tie is null, we define $n(a,i,j) = 0$ and write $a(i,j) = \varnothing$. (We choose to allow $t \leq u$ in order to accommodate discrete-time observation schemes.)

We note that for any arbitrary finite set of time intervals contained within $[0,\omega]$, there is a unique expression for the set of intervals in a form in which each pair of intervals is *strictly disjoint* (that is, for two time intervals $[t,u]$ and $[v,w]$, either $t \leq u < v \leq w$ or $v \leq w < t \leq u$); we call this form *canonical* and assume its use throughout. We refer to $a = [a(i,j)]$ as a *dynamic social network* and to $\{a_1, a_2, \ldots, a_r\}$ as a *dynamic multiple social network*.

As in the static case, we regard $\{a_1, a_2, \ldots, a_r\}$ as a set of network generators and consider dynamic analogues of the operations of composition and Boolean addition. An example of a dynamic multiple network is presented in **Table 5**. In this example, $n(a,i,j) \leq 1$, and $n(b,i,j) \leq 1$ for each pair (i,j) of actors.

Following Moody (2002), we define a composition operation for two dynamic networks a and b, which ensures that the relation ab comprises intervals for a pair (i,j) of actors in which it would be possible for some entity (e.g., an idea, a disease, or resources) to originate at i and reach j by flowing from i to some third party k along a tie labeled A and then from k to j along a tie labeled B. This definition of composition gives rise to what

Table 5 A small hypothetical dynamic multiple social network $\alpha = \{a,b\}$ on node set $N = \{1,2,3,4\}$ and time interval [0,5]

	a				b			
1	∅	[4,5]	∅	∅	∅	∅	[0,1]	∅
2	∅	∅	∅	∅	∅	∅	∅	[0,1]
3	∅	∅	∅	[4,5]	[0,1]	∅	∅	∅
4	∅	∅	∅	∅	∅	[0,1]	∅	∅

Moody termed *time-ordered* paths or walks in the dynamic multiple social network. In a recent review of temporal networks, Holme and Saramäki (2011) observed that the concept of a *time-respecting path* has emerged in a number of fields. In fact, Moody's definition for a walk labeled *AB* from *i* to *j* yields the broadest time interval over which the flow of some entity originating at actor *i* can reach actor *j* by traveling along a walk of type *A* to an intermediary *k* and then a walk of type *B* from *k* to *j*.

Specifically, if we write

$$a(i,k) = \left\{[t_1,u_1],[t_2,u_2],\ldots,\left[t_{n(a,i,k)},u_{n(a,i,k)}\right]\right\}$$

and

$$b(k,j) = \left\{[v_1,w_1],[v_2,w_2],\ldots,\left[v_{n(b,k,j)},w_{n(b,k,j)}\right]\right\}$$

then the composition *ab* of the dynamic networks *a* and *b* is defined to have ties $ab(i,j)$ in which

$$ab(i,j) = \cup_{k\in N}\left(\cup_{p=1,n(a,i,k)}\cup_{q=1,n(b,k,j)}\left[\max(t_p,v_q),w_q\right]\right)$$
$$\text{if } a(i,k)\neq\varnothing \text{ and } b(k,j)\neq\varnothing \quad \text{for some } k,$$

and

$$\begin{aligned} ab(i,j) &= \varnothing \quad \text{if } a(i,k) = \varnothing \text{ or } b(k,j) \\ &= \varnothing \quad \text{for each } k\in\{1,2,\ldots,n\} \end{aligned}$$

The logic of this expression is that for each potential third party *k*, and for each of the constituent intervals $[t_p,u_p]$ for which *i* is linked to *k* by a relation of type *A* and $[v_q,w_q]$ for which *k* is linked by a relation of type *B* to *j*, there is a possibility of flow through actor *k* to actor *j* of some entity arising at actor *i* during the period $[\max(t_p,v_q),w_q]$. We need to consider this possibility not only for all third parties *k* but also for all pairs of intervals making up $a(i,k)$ and $b(k,j)$, hence the union over both *p* and *q* as well as *k* in the expression above. As noted above, we assume following computation that $ab(i,j)$ is reexpressed in canonical form.

If, for example, $a(i,k) = \{[t,u]\}$ and $a(k,j) = \{[v,w]\}$, then the broadest time period over which flow could occur from actor *i* to actor *j* via *k* on a path of ties labeled *A* is $[\max(t,v),w]$. Importantly, this interval is smaller than or equal to $[v,w]$ and is the segment of the time period over which actor *k* is linked to actor *j*, which follows some segment of the period during which actor *i* is connected to actor *k*.

It should be noted that this form of composition is appropriate for the consideration of labeled walks as potential conduits of entities that endure in time. It is arguably less appropriate for the consideration of potential flows that are subject to various forms of dissipation (e.g., through forgetting or loss of relevance, in the case of an idea; conversion to a nonusable form in the case of resources; or cure in the case of a disease). As a result, Kontoleon et al. (2013) also consider a more general form of composition for dynamic networks in which the potential longevity of any flows along labeled walks can be reflected in the composition operation. The approach of Kontoleon et al. reflects the need articulated by Borgatti (2005) for a variety of different approaches to representing and analyzing flows and potential flows in social networks.

It is not possible to define an identity relation for the composition operation in dynamic networks just defined, but a left identity can be constructed. Define a (maximal) *left identity* dynamic network for composition as the network *l* with entries:

$$\begin{aligned} I(i,j) &= \{[0,\omega]\} \quad \text{if } i = j; \\ I(i,j) &= \varnothing, \quad \text{otherwise.} \end{aligned}$$

It follows from the definition that $la = a$ holds for all dynamic networks *a*.

A natural addition operation can also be defined for any dynamic networks *a* and *b* with

$$a(i,j) = \left\{[t_1,u_1],[t_2,u_2],\ldots,\left[t_{n(a,i,j)},u_{n(a,i,j)}\right]\right\}$$

and

$$b(i,j) = \left\{[v_1,w_1],[v_2,w_2],\ldots,\left[v_{n(b,i,j)},w_{n(b,i,j)}\right]\right\}.$$

We define

$$\begin{aligned} (a+b)(i,j) = &\left\{[t_1,u_1],[t_2,u_2],\ldots,\left[t_{n(a,i,j)},u_{n(a,i,j)}\right]\right\} \\ &\cup\left\{[v_1,w_1],[v_2,w_2],\ldots,\left[v_{n(b,i,j)},w_{n(b,i,j)}\right]\right\} \end{aligned}$$

and note that the latter can be reexpressed in canonical form as

$$(a+b)(i,j) = \left\{[x_1,y_1],[x_2,y_2],\ldots,\left[x_{n(a+b,i,j)},y_{n(a+b,i,j)}\right]\right\}.$$

We also define a null dynamic network *o* on node set *N*, which serves as an identity for the union operation on dynamic networks on *N*. The dynamic network *o* with entries

$$o(i,j) = \varnothing \quad \text{for all } i,j\in N$$

is termed the *null* dynamic network.

A natural partial order can also be defined for dynamic networks. For dynamic networks *a* and *b* with

$$\begin{aligned} a(i,j) &= \left\{[t_1,u_1],[t_2,u_2],\ldots,\left[t_{n(a,i,j)},u_{n(a,i,j)}\right]\right\} \text{ and} \\ b(i,j) &= \left\{[v_1,w_1],[v_2,w_2],\ldots,\left[v_{n(b,i,j)},w_{n(b,i,j)}\right]\right\} \end{aligned}$$

define

$$a \le b$$

if and only if, for all *i* and *j*, and for each $p \in \{1,2,\ldots,n(a,i,j)\}$, there is some $q \in \{1,2,\ldots,n(b,i,j)\}$ such that

$$v_q \le t_p \le u_p \le W_q$$

As for the static case, the operations just defined give rise to algebraic structures on dynamic multiple networks.

Definition 7

A *left dioid* is a set S endowed with binary operations, $\circ$ and $+$, and a partial order $\leq$, satisfying the following axioms:

1. *commutativity of* $+$: $a + b = b + a$, for all $a, b \in S$;
2. monoid structure under $+$: $(S,+)$ is a monoid;
3. *semigroup structure under* $\circ$ with left identity: $(S,\circ)$ is a semigroup, with left identity l such that $la = a$ for all $a \in S$;
4. *partial order*: $\leq$ is a partial order on S;
5. *absorption*: $a \circ o = o \circ a = o$, for all $a \in S$; and
6. *left distributivity of* $\circ$ *over* $+$: $a \circ (b + c) = a \circ b + a \circ c$, for all $a, b, c \in$ S.

Left dioids are described in more detail in Gondran and Minoux (2008). It can readily be demonstrated that the closure of a dynamic multiple network is a left dioid under the composition and union operations defined above.

By way of illustration, we consider the hypothetical dynamic network $\alpha = \{a,b\}$ displayed in Table 5 and construct in Table 6 the distinct dynamic networks generated by α under time-ordered relational composition. Table 7 contains the partially ordered semigroup α^* generated by time-ordered composition. It can be seen that although the pattern of nonnull entries in the dynamic multiple network of Table 5 mirrors the pattern of zero entries in the multiple network of Table 1, the structure of the monoid generated by the multiple dynamic network in Table 7 is quite different to that in Table 3. For example, $ab = ba$ is an equation in the monoid generated by the multiple social network in Table 1, but ab and ba are distinct in the partially ordered semigroup generated by the dynamic multiple social network of Table 5. This difference reflects the time-ordered nature of composition in the dynamic network and illustrates the importance of the temporal properties of the generator networks in understanding the structure of labeled walks to which they give rise.

Kontoleon et al. (2013) show how the algebraic structure of dioids may be exploited to assist in computing time-ordered paths and labeled walks in a dynamic multiple network. They construct a dioid of endomorphisms acting on the set of time intervals that allows very general composition operations. They describe application of the generalized Jacobi and Gauss–Seidel algorithms (e.g., Gondran and Minoux, 2008) to compute reachability in a dynamic social network and adapt Brandes' (2001) betweenness algorithm to a dynamic context. As they argue, the capacity to use time-ordered walks in a dynamic network is important because it allows for the construction of measures that are sensitive to the full dynamic structure of the network, moving beyond those based on an ad hoc time-slicing of the network.

Table 6 Distinct elements other than *a* and *b* in the partially ordered semigroup generated by the dynamic multiple social network $\alpha = \{a,b\}$ of Table 6

	o				ba				bb			
1	∅	∅	∅	∅	∅	∅	∅	[4,5]	[0,1]	∅	∅	∅
2	∅	∅	∅	∅	∅	∅	∅	∅	∅	[0,1]	∅	∅
3	∅	∅	∅	∅	∅	[4,5]	∅	∅	∅	∅	[0,1]	∅
4	∅	∅	∅	∅	∅	∅	∅	∅	∅	∅	∅	[0,1]

Table 7 The partially ordered semigroup α^* generated by $\alpha = \{a,b\}$ of Table 6: right multiplication table and partial order

Element	a	b	a	b	o	ba	bb
a	*o*	*o*	1	0	1	0	0
b	*ba*	*bb*	0	1	1	0	0
o	*o*	*o*	0	0	1	0	0
ba	*o*	*o*	0	0	1	1	0
bb	*a*	*b*	0	0	1	0	1

Conclusion

The algebraic structure of a multiple social network describes the relationships among labeled walks and their unions. In an analogous way, the algebraic structure of a multiple dynamic social network describes the relationships among labeled time-ordered walks and their unions. In both cases, the algebraic structure can serve one of several key purposes: (1) as the foundation for algorithm development and hence for the development of efficient computational approaches for measures in static or dynamic networks that depend on walks in those networks (e.g., Harary et al., 1965; Gondran and Minoux, 2008; Kontoleon et al., 2013); and (2) as a description of the relationship among labeled (and, where relevant, time-ordered) walks in the network, and hence as the basis for structural analysis and comparison of multiple networks (e.g., Pattison, 1993, 2009).

Social Neuroscience of the Twenty-First Century

Abstract

Social species are so characterized because they form organizations that extend beyond the individual. The goal of social neuroscience is to investigate the biological mechanisms that underlie these social structures, processes, and behaviors and the influences between social and neural structures and processes. Such an endeavor is challenging because it necessitates the integration of multiple levels. Mapping across systems and levels (from genome to social groups and cultures) requires interdisciplinary expertise, comparative studies, innovative methods, and integrative conceptual analysis.

Social Neuroscience

Social neuroscience brings together a broad variety of scientists, disciplines, and methodologies dedicated to investigating the biological mechanisms of social interaction, and thus represents an interdisciplinary scientific field that dives into the hard problem of the mutual influence of biology and social mechanisms (Cacioppo and Berntson, 1992, 2001) – a problem described by Frith and Wolpert (2004) as one of the major problems for the neurosciences to address in the twenty-first century. Based on the premise that all social behaviors are implemented biologically, this exciting and mature academic field seeks to understand (1) how biological systems implement social processes and behaviors; (2) how social structures that range from dyads, families, neighborhoods, and groups to cities, civilizations, and international alliances impact the brain and biology; and (3) how social and neural structures interact to produce these outcomes. In other words, social neuroscience investigates the interaction between social factors and the central nervous system, their manifestations, and potentially reciprocal influences across levels, from molecules to societies.

Social neuroscience and cognitive neuroscience both focus on the relationship between behavior and brain networks, but the basic perspective of each is distinct and complementary. Cognitive neuroscience views the human brain from the perspective of a solitary computing device capable of complex analyses and computations. Accordingly, attention, perception, memory, and language as an internal representational system are among the topics of interest. Social neuroscience, in contrast, views the human brain as a mobile, broadband computing device connected to others. Among the topics of interest are social learning, hierarchies, imitation, conformity, attraction, empathy, and language as a system for communication with others. According to the social brain hypothesis, the social complexities and demands of primate species have contributed to the rapid increase in neocortical connectivity and intelligence. Consistent with this hypothesis, the evolution of large and metabolically expensive brains in primates is more closely associated with social than ecological complexity (Dunbar and Shultz, 2007; Ott and Rogers, 2010), and the volume of some brain areas, such as the amygdala, correlate with the size and complexity of a person's social networks (Bickart et al., 2011).

Anecdotal evidence for the importance of both social and biological factors on outcomes such as health and well-being has existed for centuries, as the influence of social support on health was apparent even to the ancient Greeks. Hippocrates (460–370 BC) frequently prescribed 'association with friends' as a way to restore the body to its natural state of harmony and cure illness (Hothersall, 2004). In 1848, the case report of Phineas Gage, an American railroad construction foreman, documented his putative changes in personality and social behavior following damage to the ventromedial prefrontal cortex – changes that were sufficiently dramatic that his friends and acquaintances observed he was 'no longer Gage' (Damasio, 1996; Harlow, 1848; Macmillan, 2008).

Empirical evidence for the value of integrating social and biological levels of analysis accrued in animal (e.g., Harlow et al., 1965) and human (e.g., Cacioppo and Petty, 1979; Cacioppo et al., 1982) research, but the emphasis on disciplinary differentiation and specialization presented an active barrier to working across these levels. Most social scientists regarded animal and biological research as having little if anything to contribute to an understanding of suffering and problems that plagued industrialized societies (e.g., Allport, 1947; for a review, see Cacioppo, 2002). On the other hand, most biological scientists believed that social factors were irrelevant to understanding basic biological structures or functions and, even if relevant, were too complicated to be understood in the foreseeable future (e.g., Scott, 1991). It was in this context that Cacioppo and Berntson (1992) proposed the doctrine of multilevel analyses (see below) and the perspective of 'social neuroscience' as a multilevel, integrative field.

In research that followed, social species were found to fare poorly when forced to live solitary lives (Cacioppo et al., 2011). Humans, born to the longest period of abject dependency of any species and dependent on conspecifics across the lifespan to survive and prosper, do not fare well whether they are living solitary lives or whether they simply perceive that they live in isolation (e.g., Luo et al., 2012; Perissinotto et al., 2012). In an illustrative study, Caspi et al. (2006) found that perceived social isolation in adolescence and young adulthood predicted how many cardiovascular risk factors (e.g., body mass index, waist circumference, blood pressure, and cholesterol) were elevated in young adulthood, and that the number of developmental occasions (i.e., childhood,

adolescence, and young adulthood) at which participants were lonely predicted the number of elevated risk factors in young adulthood. Perceived isolation has also been associated with the progression of Alzheimer's disease (Wilson et al., 2007), obesity (Lauder et al., 2006), increased vascular resistance (Cacioppo et al., 2002a), elevated blood pressure (Cacioppo et al., 2002a; Hawkley et al., 2006), increased hypothalamic pituitary adrenocortical activity (Adam et al., 2006; Steptoe et al., 2004), less salubrious sleep (Cacioppo et al., 2002b; Pressman et al., 2005), diminished immunity (Kiecolt-Glaser et al., 1984; Pressman et al., 2005), reduction in independent living (Russell et al., 1997; Tilvis et al., 2000), alcoholism (Akerlind and Hörnquist, 1992), depressive symptomatology (Cacioppo et al., 2006; Heikkinen and Kauppinen, 2004), suicidal ideation and behavior (Rudatsikira et al., 2007), and altered gene expression including the underexpression of genes bearing anti-inflammatory glucocorticoid response elements (GREs) and overexpression of genes bearing response elements for proinflammatory nuclear factor κB/Rel transcription factors (Cole et al., 2007, 2011). Nonhuman social species from fruit flies to apes also show similar deleterious biological effects of social isolation (e.g., Makinodan et al., 2012; Ruan and Wu, 2008).

The questions posed by the social neuroscience perspective, methodological, and quantitative developments, and the promise of more comprehensive theories inspired a new generation of scientists to pursue a more complex picture of behavior and biological functioning. By its 20th anniversary, social neuroscience had become an active field of research across the globe, fueled by the establishment of societies and journals to advance and foster scientific research, education, and clinical applications.

Doctrine of Multilevel Analyses

Social species are so characterized because they form organizations that extend beyond the individual. The goal of social neuroscience is to investigate the biological mechanisms that underlie these social structures, processes, and behaviors and the influences between social and neural structures and processes. Such an endeavor is challenging because it necessitates the integration of multiple levels. Mapping across systems and levels (from genome to social groups and cultures) requires interdisciplinary expertise, comparative studies, innovative methods, and integrative conceptual analysis (Cacioppo and Decety, 2011). Cacioppo and Berntson's (1992) doctrine of multilevel analyses emphasized the importance of using multilevel analyses to test hypotheses across their different levels of organization and specified three illustrative principles one can use to investigate key questions in social neuroscience along the continuum of organizational levels.

The principle of multiple determinism specifies that behaviors can have multiple antecedents within or across levels of organization. For instance, although immune response was once thought to reflect only physiological responses to pathogens or tissue damage, a more complete understanding of immunity has led to demonstrations of how a person's perceptions of his or her close personal relationships may impact inflammation and immunity (e.g., Kiecolt-Glaser et al., 2010). Psychosocial stress, operating through the brain's perception of the meaning of events, can also increase proinflammatory cytokine production in the absence of infection or injury. Animal research has revealed related findings in mice: exposure of mice to 2 weeks of isolation enhances tumor liver metastasis in part via its suppressive effect on the immune system of the host (Wu et al., 2000). One implication of this principle is that comprehensive theories of social phenomena require a consideration of multiple factors from various levels of organization – e.g., from the biological and individual's level to the social level (Cacioppo and Ortigue, 2011). A second implication is that many-to-many mappings between elements across proximal levels of organization become increasingly complex as the number of intervening levels of organization increases. Accordingly, the articulation of these mappings and mechanisms underlying a given multilevel observation may be simpler when working across proximal rather than distal levels of organization.

The principle of nonadditive determinism specifies that properties of the whole are not always readily predictable by the simple sum of the (initially recognized) properties of the parts (Cacioppo and Berntson, 1992). For instance, the behavior of nonhuman primates was examined following the administration of amphetamine or placebo (Haber and Barchas, 1983). No clear pattern emerged until each primate's position in the social hierarchy was considered. When this social factor was taken into account, amphetamines were found to increase dominant behavior in primates high in the social hierarchy and to increase submissive behavior in primates low in the social hierarchy. A strictly biological (or social) analysis, regardless of the sophistication of the measurement technology, may not have unraveled the orderly relationship that existed.

Finally, the principle of reciprocal determinism specifies that there can be mutual influences among biological and social factors in determining behavior (Cacioppo and Berntson, 1992). For example, maternal behavior can alter expression of genes through a process of DNA methylation, and genes altered in this way then can affect subsequent maternal behavior (Zhang and Meaney, 2010). One important implication is that comprehensive accounts of human behavior cannot be achieved if the biological, cognitive, or social levels of organization are considered unnecessary or irrelevant.

Social neuroscience also flourishes because of an increasing number of sophisticated methods and techniques that have been developed in the past two decades. This point is discussed next.

Techniques Used in Social Neuroscience

To investigate the mutual influence of biological and social mechanisms, social neuroscientists, ranging from physicists to psychologists, epidemiologists to neurologists, philosophers to neurobiologists, and entomologists to zoologists, have begun to work together in interdisciplinary scientific teams using animal models, patients studies, and research on healthy individuals. These interdisciplinary collaborations have capitalized on a variety of methods and techniques ranging from

behavioral studies of implicit processes in lesion and split-brain patients to volumetric and neuroimaging studies across scales of neural organization in chimpanzees or healthy humans to cellular and molecular techniques in genetics and epigenetics. Even developed techniques such as meta-analyses and electroencephalography have seen upgrades that, for instance, permit investigations of the source and chronoarchitecture of the neural substrates of social processes (e.g., He et al., 2009; Ito et al., 2004; Ortigue et al., 2010). Importantly, the development of experimental manipulations of neural processes in humans through, for instance, the use of transcranial magnetic stimulation and neurotransmitter agonists and antagonists has also helped determine the causal significance of specific neural regions in social cognition, emotion, and behavior. Finally, increases in computational speed and capacities are increasingly simplifying the problem of addressing questions across levels of organization that involve large datasets and/or previously computationally prohibitive simulations or analyses.

Prospects

Interdisciplinary collaborations are a cornerstone of social neuroscience endeavors. A decade ago, the field was characterized by some as correlating social and cognitive functions with regions of brain activation using functional neuroimaging. The field has always had a broader foundation, however, and social neuroscience is now recognized as drawing on research on animals and humans, with phenomena at multiple levels of organization measured and/or manipulated to go beyond the specification of association across levels to specify the mechanisms operating at and between each of the levels of organization pertinent to an association. The manifold disciplinary expertise for such multilevel investigations is increasingly beyond the reach of individual scholars, so interdisciplinary teams of scientists are increasingly common.

Furthermore, the twenty-first century presents its own unique array of questions. For instance, the development and accessibility of the Internet have transformed major aspects of the social environment, including how and where people study, meet, shop, and interact. Understanding how online interactions are similar to and different from face-to-face social interactions and how they might best be performed to benefit users across the lifespan is of particular relevance to a world growing more and more dependent upon the Internet and social networking sites for social interactions. And the century is still young. What the short history of social neuroscience has shown is that the number of social neuroscience papers that appeared in multidisciplinary science journals nearly doubled in the first decade of the field's existence and that the field has attracted some of the best and the brightest scientists across a wide range of scientific disciplines, with high rates of citation of social neuroscience articles in their dominant disciplinary journals (Matsuall et al., 2011). By bridging the gap between animal and human studies, social neuroscience has contributed to the understanding of the mechanisms by which the social world (and its disorders) impacts health, well-being, and longevity. The successes that social neuroscience has already met in its first two decades of existence suggest a promising future as it opens a critical avenue for a better understanding of the biology of connected minds. A multilevel integration of the social, biological, and cognitive factors known to determine behavior could also provide scientists and practitioners with new therapeutic interventions to address acute and chronic individual, communicative, and social disorders such as autism, psychopathy, and social phobias (e.g., see reviews by Cacioppo et al., 2007; Cacioppo and Ortigue, 2011). The road ahead is not only replete with conceptual challenges and methodological issues, but also promises exciting scientific discoveries. In short, the twenty-first century is an exciting time in which to be a social neuroscientist.

Social Ontology

Abstract

Social ontology is the study of the nature of social being; those characteristics of reality that are necessarily dependent on human social interaction. There are two general approaches to social ontology in the literature. The first focuses on the ontological elaboration of theoretical concepts or assumptions of a particular author, theory, or approach. The second articulates a general conception of social ontology in which to anchor current or future theoretical and empirical research programs. This article introduces some major contributions to both approaches and discusses differences between them.

What is Social Ontology?

Ontology is the study of the nature of being. Social ontology is the study of the nature of social being; those characteristics of reality that are necessarily dependent on human social interaction. One prominent justification for the study of social ontology is that the social sciences have regularly imported methods of analysis from the natural sciences or mathematics without considering whether such methods are well suited to their object of study. A deeper analysis of that object has the potential to inform both methodological reflection and theory development within the social sciences.

Use of the term social ontology has increased markedly since the turn of the twenty-first century across the social sciences. In some disciplines including sociology, organization studies, and international relations, social ontology is sufficiently prominent to be invoked in key theoretical and meta-theoretical debates. However, the proliferation of the jargon associated with social ontology does not automatically indicate a coherent research paradigm: there is diversity both within and between the dominant positions in the field.

Even the term 'social ontology' contains a fundamental ambiguity which requires further clarification. Not only does it refer to the study of the nature of social reality, but it also refers to a specific conception of social reality. Thus a particular author or school of thought can be said to articulate, and defend or criticize 'a social ontology.' This ambiguity has led to a distinction within the literature between work that focuses on the ontological elaboration of theoretical concepts or assumptions of a particular author, theory or approach, and scholarship whose goal is to articulate a general conception of social ontology in which to anchor current or future theoretical and empirical research programs. In the remainder of this contribution, I shall refer to the first approach as 'scientific ontology' and the second as 'philosophical ontology,' though there are several alternative classifications in the literature. These two approaches will be discussed in greater depth in Sections Scientific Ontology and Philosophical Ontology respectively.

As suggested by the widespread use of philosophical jargon and the investigation of explicitly philosophical themes by social ontologists, there is a clear connection between both of these approaches and the philosophical literature. In particular, both approaches to ontological research can be seen as an outgrowth of scientific realism in analytic philosophy. Starting in the 1970s, realists provided a critical impetus by challenging logical positivism and empiricism in the philosophy of science, by implication threatening the dominance of positivist-inspired philosophy of social science. More importantly perhaps, realists also provided a general philosophical approach that retained a commitment to causal explanation as the cornerstone of the scientific endeavor – a position that hermeneutic approaches to the social sciences frequently rejected.

It is nevertheless entirely inaccurate to view social ontology as the top-down imposition of philosophical concepts and categories onto the social sciences. In fact, the current literature is dominated by practicing social scientists rather than professional philosophers, and contributions typically reflect the preoccupations of the fields or disciplines to which they contribute. So, for example, the economist Tony Lawson (1997) uncovers the ontological presuppositions implicit in the mathematization of economics, whilst the sociologist Margaret Archer (1995) addresses those of the structure–agency debate in social theory. Indeed, social ontology has recently been described as 'philosophy for social science,' rather than the philosophy of social science (Lawson et al., 2007: pp. 1–14).

Scientific Ontology

The main objective of the scientific ontology literature is to identify and elaborate the ontological presuppositions of social scientific concepts and categories. In so doing, social ontologists echo Willard Van Orman Quine's view that theory construction necessarily involves ontic commitments and that the analysis of these commitments is a legitimate domain of philosophical enquiry (Quine, 1948). Scientific ontologists need not, however, commit themselves to any particular worldview from which to judge or criticize their targets.

Scholars engaged in scientific ontology are usually not system builders, rather they see themselves as contributing to a better understanding of the basic categories of social analysis. There are, however, at least two different ways in which scientific ontology can engage with these categories:

1. By teasing out the implicit ontological commitments of a particular author, model, theory, or school of thought.

2. By engaging in the ontological elaboration or exploration of a social scientific concept or category, using extant theory as a reference or starting point.

The first strand is principally descriptive, whilst the second engages more directly in theoretical debates within the social sciences. Some influential contributors to the field clearly privilege the first strand, stressing their role as critically reflective interpreters of disciplinary discourse rather than direct participants in theoretical debates (Maki, 2001: pp. 1–14). Others argue more forcefully for the importance of the second strand (Pratten, 2007).

The purpose of teasing out the implicit ontological commitments of an author's contribution is particularly important in social scientific disciplines where those authors are the figureheads of schools of thought. Studies of this first type can also aim to elaborate or complete an ongoing exercise in the history of ideas by focusing attention on the ontological aspects of a well-known and influential contribution (Fleetwood, 2002). Nevertheless, trying to identify the ontological commitments of an (sometimes long dead) author is an extremely difficult task that will almost inevitably produce partial and tentative conclusions.

By comparison, analysis of the presuppositions of specific theories or models promises more decisive results, so long as the target theory is well articulated. The general strategy is to ask some variant of the following question: "What would the world have to look like for theory x to be true?" This is the strategy adopted by Lawson in his discussion of modeling in mainstream economics (Lawson, 1997: pp. 3–25). He begins by noting that mainstream economics endorses a conception of science that sees its objective as the production of lawlike generalizations of the form "whenever event x then event y." He goes on to demonstrate how the methods used by economists presuppose a world populated by isolated atoms interacting in what he calls a closed system (a system in which the empirical regularities required for these laws to be true exist). This ontological analysis of the presuppositions of current mainstream modeling practice is the foundation of his subsequent critique of the discipline. Scientific ontology can also be used to facilitate internal critique. This is the strategy adopted by Archer in her analysis of Anthony Giddens' 'structuration theory' (Archer, 1995: pp. 93–134). She argues that Giddens' elision of the categories of structure and agency – itself an attempt to avoid traditional reified conceptions of social structure – leads him to adopt a flat ontology of social practices. This ontology can no longer accommodate an account of the interaction between structural factors and individual action, which is seen as a central concern of social theory.

The second strand of scientific ontology usually starts with extant social scientific theory as well, but its objectives are somewhat different. Rather than uncovering the presuppositions of an author or theory, this strand of ontological research seeks to elaborate important categories and concepts. Thus, social ontologists have contributed to discussions of the nature of institutions (Lawson, 2003), rules and conventions (Latsis, 2005; Al-Amoudi, 2010) and technology (Faulkner and Runde, 2009; Lawson, 2009) amongst many other topics. Contributors to these debates have engaged directly with social–scientific research by pointing out weaknesses, tensions, or incoherence implicit in the use of these concepts and attempting to resolve them, thus providing the potential foundations for new theories.
